[13] This does not preclude, however, an additional future non potable supply being made available to the project in the City's or EID's service area.

"Low Density Residential" land-use category was assigned a unit demand factor of 0.65 acre-feet per dwelling unit per year (af/du/yr), while the "Very Low Density Residential" category was assigned a unit demand factor of 0.59 af/du/yr.[14] The results of the 2003-2008 meter reading study support the use of 0.59 and 0.65 af/du/yr for the City's existing service area. The 2003-2008 meter-reading project entailed reading the meters of 3,909 single-family homes in August 2003 and again in July 2008 and calculating an annual average based upon the cumulative total. The average annual unit demand was 0.67 af/du/yr for all samples and 0.63 af/du/yr when the highest and lowest ten percent of samples were removed. These figures therefore support use of a historic figure between 0.60 and 0.70 af/du/yr as a basis for further refinement of the unit demand factors for both the Folsom SPA – PPA and Folsom SPA - RHA.

While the division between indoor and outdoor unit demands in the City of Folsom's meter study is not certain because dedicated irrigation meters did not exist on the accounts used for the study, it is possible to derive both indoor and outdoor unit demands using the meter data. The outdoor component calculation uses reference evapotranspiration (ETo), plant factor, and irrigation efficiency numbers that are appropriate for the City of Folsom's geography and climate.[15] In the City of Folsom, ETo is 53 inches per year, the average plant factor throughout a residential landscape is 0.7 and irrigation efficiency is about 70%.[16] Thus, total average applied water use to meet

[14] In the 2005 UWMP, the unit demand factor for the "Low Density" Residential category was comprised of an indoor factor of 0.20 af/du/yr and an outdoor factor of 0.45 af/du/yr. For the "Very Low Density" Residential category the unit demand factor was comprised of an indoor factor of 0.20 af/du/yr and an outdoor factor of 0.39 af/du/yr. These factors do not account for system losses.

[15] "Reference evapotranspiration" (ETo) is a standard measure of the environmental conditions, which affect the water use of plants. It is typically derived by measuring the evapotranspiration of cool-season grass and is expressed in inches over a specific period of time. A "plant factor" is used to determine plant water use relative to ETo. "Plant factors" are assigned to low, moderate and high water use plants. "Irrigation efficiency" (IE) is the measurement of the amount of water used by a plant divided by the amount of water applied.

[16] ETo is measured at the California Irrigation Management Information System (CIMIS) station located in Fair Oaks, California. The plant factor of 0.7 reflects the fact that the predominant landscape planting in the residential sector is cool-season grass, which has a plant factor of 0.8. A slight reduction is made to 0.7 to account for trees, shrubs, native landscapes, and non-living landscape cover. An irrigation efficiency of 70% was selected because, according to UC Cooperative Extension and the Department of Water Resources, "A representative range of efficiencies for landscape systems is proposed ... to be from 65% to 90%," and "A system which is well designed and operated can have an efficiency range of 80% to 90%." Because historic residential unit demand was estimated for homes built no later than 2003, it is unlikely the systems would be considered "well designed and operated" seven years later. Therefore, an irrigation efficiency rate on the lower end of the range was selected. *A Guide to Estimating Irrigation Water Needs from Landscape Plants in California*, University of California Cooperative Extension and California Department of Water Resources, August 2000.

outdoor demand is calculated at 4.30 acre-feet per acre (af/ac).[17] As shown in **Table 2-1**, assuming four units per acre (the mid range between the "Very Low" and "Low Density" categories), up to 35% building coverage, 15% for roads and right of ways, and about 10% for hardscapes, then landscape area would be about 40% per unit.[18] Total landscape demand per unit would be approximately 0.39 acre-feet per unit per year (af/unit/year).

Table 2-1
Outdoor Unit Demand Validation

Outdoor Unit Demand Derivation	
Parcel Area (sf)	10890
Landscape Area (sf)	3920
Landscape Area (ac)	0.09
Landscape Water Demand (af/yr)	0.39

If total annual unit demand is 0.61 af/unit/yr, the indoor demand component of total demand is approximately 0.22 af/unit/year after subtracting the outdoor demand component shown in **Table 2-1**. If there are 2.83 persons per unit per the 2005 UWMP, the indoor demand per person would be about 70 gallons/day, as shown in **Table 2-2**.

Table 2-2
Indoor Unit Demand Validation

Baseline Indoor Unit Demand	
Indoor Unit Demand (af/unit/yr)	0.22
Persons Per Unit	2.83
Indoor Per Capita Demand (gpcd)	69.4

[17] Applied Water (AW) = (ETo * Plant Factor)/IE. To convert ETo from inches to cubic feet, divide by 12. To convert cubic feet to gallons multiply by 7.481 gallons/cubic foot. To convert to gallons per acre, multiply by 43,560 ft/ac. To convert from gallons to acre-feet, divide by 325,851. (((((53/12)*7.481)*43560)/325851)*.7)/.7= 4.3 af/ac. This method does not account for "effective precipitation," (where effective precipitation is defined as the portion of annual rainfall that contributes to the outdoor demand) which may further reduce applied water. This constitutes a conservative estimate of applied water demand. For comparison, EID data provided by EID Staff indicates much lower outdoor unit demand factors (e.g. reported use of recycled water for recreational turf areas is about 2.2 acre-feet/acre). For purposes of the Folsom SBA – PPA outdoor demands, the higher outdoor factor is used as a baseline. The conservative estimate identified here is used for planning purposes.

[18] The estimate of landscaped area assumes the single-family lots in the meter study are similar to the City of Folsom's *Single Family Dwelling, Medium Lot District* category, which requires 10,000 square foot lots and maximum building coverage of 35%.

Thus, 70 gallons/day will be used as the base indoor per capita demand for the Folsom SPA – PPA and Folsom SPA – RHA, with refinements as explained in **Section 2.2.1.1** and **Section 6.1.**[19]

2.1.2 Regional Residential Unit Demand Factors

Dwelling unit demand factors for the Folsom SPA – PPA and Folsom SPA – RHA water demand estimates are also based on regional unit demand figures. Regional residential unit demand factors are presented in **Table 2-3** for comparison with unit demand factors used by the City of Folsom in its 2005 UWMP. Notably, EID, the City of Roseville and the Placer County Water Agency (PCWA) provide metered water service and Sacramento County Water Agency (SCWA) is a partially metered jurisdiction.[20] Much of the housing product mix in the El Dorado Hills portion of EID's service area, the City of Roseville, PCWA and SCWA service areas is similar to that in the City of Folsom. Overall, average unit demand for these jurisdictions are comparable to the City of Folsom's historic unit demand. Instances where demand factors are lower could be partially due to volumetrically billing in the residential sector, effective precipitation, smaller percentages of system losses, and other factors affecting demand variability. Because the City of Folsom plans to provide metered water service to single-family residential units in the Folsom SPA, unit demand factors below the unit demands factors used in the City of Folsom's 2005 UWMP are appropriate. Also, the fact that the average figures were developed based upon water use across a wide mix of housing ages and product types provides support for the case that a more modern uniform housing product with current conservation infrastructure - such as that which will exist in the Folsom SPA - should have lower unit water demand factors for each respective residential density category than the unit water demands used in the City of Folsom's 2005 UWMP.

[19] This indoor baseline per capita demand value is further supported by EID's historic data for "Single-Family Dual Potable" water use as reported in its annual Water Resources & Services Reliability Report (2006 through 2009, see Appendix Table A). In these annual reports, the estimated indoor use averages less than 0.20 acre-feet per dwelling unit.

[20] The PCWA service area is the geographic boundary in Placer County throughout which PCWA carries out a broad range of responsibilities including water resource planning and management, retail and wholesale supply of irrigation water and drinking water and production of hydroelectric energy. The SCWA service area includes eight zones of benefit. Each zone encompasses a unique geographic area of benefit to achieve SCWA's desired water management goals, including storm and floodwater control, diversion, storage and delivery of surface water, and regulation, production and distribution of groundwater. EID values are from Appendix Table A from recent Water Resources & Services Reliability Reports available on EID's website.

Table 2-3[21]
Regional Residential Unit Water Demand Comparison

Folsom SPA Land Use	Unit Density (units/ac)	Unit Water Demand Factors, AF/DU					
		Roseville	PCWA	SCWA	EID	Average	2005 UWMP
Residential							
Single Family	3.9	0.84	0.64	0.68	0.74	0.73	0.65
Single Family High Density	6.9	0.59	0.55	0.68	n/a	0.61	0.65
Multi Family Low Density	11.9	0.37	0.48	0.29	0.34	0.37	0.56
Multi Family Medium Density	17.9	0.33	0.35	0.29	0.34	0.33	0.40
Multi Family High Density	25	0.21	0.21	0.15	n/a	0.19	0.30
CCD-Residential	12	0.21	0.21	0.15	n/a	0.19	0.30

2.1.3 Current and Future Mandates

External forces may drive the City of Folsom to adopt policies that ensure future residential development in the City of Folsom achieves lower unit water demands than those seen historically in the City of Folsom. **Section 2.1.3** identifies and describes the key drivers that support use of unit demand factors that are lower than historically seen in the City of Folsom and either similar to or even more aggressive than those in neighboring jurisdictions.

2.1.3.1 Water Conservation Objectives

On November 10, 2009, Governor Arnold Schwarzenegger signed SBX7 7 which now requires each urban water supplier to select one of four water conservation targets in California Water Code § 10608.20 with the statewide goal of achieving a 20-percent reduction in urban per capita water use by 2020. The City of Folsom is not yet required to state a water conservation target pursuant to SBX7 7, but will do so in its 2010 Urban Water Management Plan (2010 UWMP). Pursuant to SBX7 7, the City of Folsom's deadline for adopting its 2010 UWMP is July 1, 2011. (CWC § 10608.20(a)(1), (i)).

[21] The unit water demands are the estimated end-use unit water demands only and do not include a non-revenue water component. Non-revenue water (NRW) is generally defined as water that has been produced (treated to accepted water quality standards for drinking water) and is "lost" before it reaches the customer. Losses can be real, through leaks, or apparent, through meter inaccuracies or unknown or unbilled connections and uses (e.g. fire hydrant flushing and construction water).

As required by SBX7 7, the city's ultimate target will require reductions in per capita urban water use from past levels. To reach its ultimate target under SBX7 7, the City of Folsom probably will need to institute water conservation measures in its existing service area, and also require new service areas to use efficient indoor infrastructure and landscape features. The state's intent is to achieve a statewide 20-percent reduction in urban per capita water use by 2020. SBX7 7's mandates to the City and the City's opportunity to help achieve the state's goal by requiring that development in the Folsom SPA incorporate state-of-the-art efficiency measures all indicate that per unit water demands under the Folsom SPA – PPA (and the Folsom SPA – RHA) will be at least 10% below historic per capita unit demand factors in the City's existing service area. The reduction will be reflected in the unit demand factors identified in **Section 2.2** and **Section 6.1**.

2.1.3.2 Indoor Infrastructure Requirements

In January 2010, the California Building Standards Commission adopted the statewide mandatory Green Building Standards Code (CAL Green Code) which will require the installation of water-efficient indoor infrastructure for all new projects beginning on January 1, 2011. CAL Green Code is currently in draft form and will become law on January 1, 2011 when it is incorporated into Title 24 of the California Code of Regulations.[22] The CAL Green Code will apply to the planning, design, operation, construction, use and occupancy of every newly constructed building or structure. Because the Folsom SPA will be applying for building permits from the City of Folsom after January 1, 2011 and the project will include new "buildings and structures" under the CAL Green Code, it will need to satisfy the indoor water use infrastructure standards necessary to meet the CAL Green Code.

The CAL Green Code requires residential and nonresidential water efficiency and conservation measures for new buildings and structures that will reduce the overall potable water use in the building by 20%. The 20% water savings can be achieved in one of the following ways: (1) installation of plumbing fixtures and fittings that meet the 20% reduced flow rate specified in the CAL Green Code, or (2) by demonstrating a 20%

[22] The CAL Green Code will appear as Part 11 in Title 24 on January 1, 2011. All references in this WSA will be to the Chapter and Section numbers that appear in the Draft document which may be obtained by visiting the California Building Standards Commission web site at: http://www.documents.dgs.ca.gov/bsc/documents/2010/Draft-2010-CALGreenCode.pdf.

reduction in water use from the building "water use baseline."[23] This WSA assumes that the residential and nonresidential buildings constructed for the Folsom SPA will satisfy one of these two requirements. To be conservative, this WSA assumes that the water savings attributable to installation of the required infrastructure will provide indoor water savings of at least 10% compared to existing infrastructure standards – but not the full 20% considered above.

2.1.3.3 California Model Water Efficient Landscape Ordinance

In 2006, the California Legislature enacted, and the Governor signed, the Water Conservation in Landscaping Act (Gov. Code §§ 65591-65599), which requires the Department of Water Resources to update the Model Water Efficient Landscape Ordinance (MWELO). On September 10, 2009, the Office of Administrative Law (OAL) approved the updated MWELO, which requires that a local agency adopt the provisions of the MWELO. Because the City of Folsom is a "local agency" under the MWELO, it must require "project applicants" to prepare plans consistent with the requirements of MWELO for review and approval by the City of Folsom. The City of Folsom is in compliance with this state law.

The MWELO provisions likely to have a significant effect on the landscape design and resulting outdoor water demand include preparation of a Landscape Design Plan with a water budget that is 70% of reference evapotranspiration.[24] The provisions of the MWELO are applicable to new construction with a landscape area greater than 2,500 square feet.[25] The MWELO "highly recommends" use of a dedicated landscape meter on landscape areas smaller than 5,000 square feet, and requires weather-based irrigation controllers or soil-moisture based controllers or other self-adjusting irrigation controllers for irrigation scheduling in all irrigation systems.[26] The MWELO provides a

[23] See **Appendix D** which contains Chapter 4 and Chapter 5 from the Draft CAL Green Code. For Residential construction, Section 4.303.1 provides the residential water conservation standard and Table 4.303.2 identifies the infrastructure requirements to meet this standard. Table 4.303.1 and Worksheets WS-1 and WS-2 are to be used in calculating the baseline and the reduced water use if Option 2 is selected. For non-residential construction, Section 5.303.2 provides the water conservation standard as well as the baseline and reduced flow rate infrastructure standards. Note that Worksheets WS-1 and WS-2 incorporate both residential and non-residential fixtures, yet the water use is still to be analyzed by "building or structure" as specified in Chapter 1, Section 101.3.

[24] California Code of Regulations (CCR), Tit. 23, Div. 2, Ch. 27, Sec. 492.4. The MWELO provides the local agency discretion to calculate the landscape water budget assuming a portion of landscape demand is met by precipitation, which would further reduce the outdoor water budget. For purposes of this WSA, precipitation is not assumed to satisfy a portion of the outdoor landscape requirement because the determination of an appropriate effective precipitation factor is highly uncertain given the various landscape slopes, terrain composition, concurrent watering schedules, etc.

[25] CCR Tit. 23, Div. 2, Ch. 27, Sec. 490.1.

[26] CCR Tit. 23, Div. 2, Ch. 27, Sec. 492.7(a)(1)(A)-(B).

methodology to calculate total water use based upon a given plant factor and irrigation efficiency.[27] Finally, MWELO requires the landscape design plan to delineate hydrozones (based upon plant factor) and then assign a unique valve for each hydrozone (low, medium, high water use).[28]

It is difficult to predict the ultimate impact of the MWELO requirements on water demand. While the requirement is for development of a landscape design plan that uses plants and features that are estimated to use no more than 70% of ETo, some provision must be made for the inherent tendency to overwater even with irrigation controllers installed, piecemeal changes in landscape design, reductions in irrigation efficiency through product use, and limited resources for enforcement in the absence of dedicated irrigation meters.

For these reasons, outdoor water use is assumed to be about 85% ETo over a long-term period. 85% of ETo was selected based on a study that supports the assumption that customers tend to apply 16% more water to the landscape than it actually needs.[29] While weather-based irrigation controllers may reduce this number such that only about 2% more water is being applied than is needed, some consideration needs to be made for the factors described above that will impact water use, outside of a controlled study, even when using a weather-based irrigation controller. These factors will likely result in overuse somewhere between 2% and 16%. Given the uncertainty regarding these impacts, the "overuse" percentage of 16% was used to adjust the MWELO Landscape Plan requirement of 70% of ETo. Dividing 70% by 84% (difference between 1.0 and .16) results in an adjusted figure of approximately 85%.

2.1.3.4 Metering and Volumetric Pricing

In 2003, the California Legislature enacted, and the Governor signed, legislation that set in motion the requirement for the City of Folsom and other purveyors to install meters on all service connections to residential and nonagricultural commercial buildings constructed prior to January 1, 1992. As a result, Water Code § 526 now requires the City to charge for water based upon the actual volume of water delivered by March 1,

[27] In calculating Estimated Total Water Use, the MWELO requires use of at least a 71% irrigation efficiency factor. Assuming 71% irrigation efficiency, the average plant factor must be 0.50. It would be possible to stay within the water budget if the average plant factor were higher than 0.50 by designing a system with an irrigation efficiency higher than 71%. Again the relationship between a Plant Factor (PF) and Irrigation Efficiency (IE) in the Applied Water formula is: AW=(ETo*PF)/IE.

[28] CCR Tit. 23, Div. 2, Ch. 27, Secs. 492.3(a)(2)(A) and 492.7(a)(2).

[29] http://www.irwd.com/Conservation/FinalETRpt[1].pdf.

2013. Assuming construction of the Folsom SPA water infrastructure occurs in 2011, and water demand is realized in 2013, the City will be billing the Folsom SPA water users on a volumetric basis by the time water service commences, which could ultimately result in unit water demand factors less than those seen historically in the City of Folsom.

The California Urban Water Conservation Council (CUWCC) recommends assuming a 20% water savings for accounts with meter retrofits and volumetric rates.[30] Twenty percent is an appropriate level of water savings when these measures are applied to existing residential accounts. With new development such as that proposed by the Folsom SPA – PPA (and the Folsom SPA – RHA), however, metering and volumetric rates are unlikely to result in 20% reductions in demands that would otherwise occur in the affected units because those units would be built with more modern infrastructure and more efficient landscape design. Accordingly, based on the CUWCC's 20% standard and the difference between development analyzed in this WSA and existing communities to which the CUWCC's standard generally applies, this WSA conservatively assumes that per unit water demands for new units built in the Folsom SPA that are metered initially will be 10% lower than per unit demands in the existing City service area.

2.1.3.5 California Urban Water Conservation Council and Water Forum Agreement Conservation Element Best Management Practices

The City of Folsom is a signatory to the CUWCC Best Management Practices (BMP) Memorandum of Understanding (MOU). The City is also a signatory to the Water Forum Agreement (WFA), under which the City of Folsom would implement the WFA Conservation Element. Both the CUWCC MOU and the WFA Conservation Element commit the City of Folsom to implementing best management practices designed to achieve water conservation across existing demand sectors. While many of the CUWCC BMPs are focused on retrofitting existing infrastructure, some of the BMPs could be valuable for the City of Folsom as they relate to water conservation efforts in new developments such as the Folsom SPA.

In 2009, the WFA updated the WFA Conservation Element. Under that revised Element, signatories would replace their respective WFA water conservation plans with the

[30] BMP 1.3, Memorandum of Understanding Regarding Urban Water Conservation in California, California Urban Water Conservation Council, December 10, 2008.

CUWCC MOU, including the CUWCC BMPs. Thus, for this Folsom SPA WSA, it is assumed that the City of Folsom will be implementing the CUWCC BMPs exclusively.

Some of the CUWCC BMPs that support using per unit demands in the Folsom SPA that are lower than such demands in the City's existing service area include Landscape Surveys (BMP 3), which could be designed for the Folsom SPA in such a way as to try to ensure the MWELO Landscape Design requirements remain in place in the field.[31] BMP 3 also requires interior surveys for Single and Multi-Family Residential customers, which could help determine whether customers are continuing to use water-efficient indoor appliances (e.g., those meeting the CAL Green Code specifications discussed in **Section 2.1.3.2**), and would also provide an opportunity for the City of Folsom to tailor its incentive programs to encourage continued use of water-efficient appliances.[32]

Also, the CUWCC recommends identifying opportunities for installation of dedicated irrigation meters, monitoring progress through billing, and then providing site-specific assistance for accounts 20% over budget. (CUWCC BMP 5) Taking the CUWCC recommendation one step further, the recently adopted CAL Green Code requires installation of separate meters or submeters in nonresidential construction landscapes that are between 1000 and 2500 square feet. Thus, irrigation submeters will be in place at many, if not all, nonresidential sites. The City of Folsom can use this meter data and provide site-specific assistance which should help maintain a level of water use consistent with its water use planning assumptions.

Also, as a signatory to the CUWCC MOU, the City of Folsom conducts public information campaigns and school education programs.[33] These educational campaigns will help reinforce water conservation oriented behavior in the Folsom SPA which can help

[31] CUWCC BMP 3 provides that MOU signatories should perform site-specific landscape water surveys that shall include checking the irrigation system and timers for maintenance and repairs; estimating landscaped area; and developing a customer irrigation schedule based on precipitation, climate and landscape conditions.

[32] CUWCC BMP 3 specifically provides that an MOU signatory should offer site-specific leak detection assistance, including a water conservation survey, water efficiency suggestions and/or an inspection, as well as providing WaterSense rated showerheads and faucet aerators.

[33] CUWCC BMP 2.1 provides that a signatory should "Implement a public information program to promote water conservation, including providing speakers to employers and at public events, providing information on customers' bills showing use for the last billing period compared to the same period the year before." This BMP also requires a messaging campaign. BMP 2.2 requires implementation of a school education program to promote water conservation, including working with schools to provide instructional assistance, educational material and classroom presentations. Both of these BMPs provide for a regional agency to undertake the educational campaigns. The City of Folsom takes advantage of this provision by supporting the Regional Water Authority's efforts on behalf of purveyors in the Sacramento County region.

minimize year-round water use indoors and moderate outdoor use during the peak irrigation season.

Two additional BMPs that will help moderate water demands in the Folsom SPA are (1) the use of a water conservation coordinator, and (2) enactment and enforcement of a water waste prohibition.[34] The City of Folsom currently has both a water conservation coordinator and an adopted water waste ordinance.[35] Both will have an impact on the Folsom SPA, because upon the SPA's annexation, the coordinator will be assigned to manage water conservation programs and city staff will be authorized to enforce the ordinance.

The CUWCC BMPs should have a long-term impact on the City of Folsom's ability to manage water use throughout the Folsom SPA. Through targeted outreach the City of Folsom can encourage continued customer use of highly efficient appliances and irrigation systems, emphasize the need to retain efficient landscape plantings, and also minimize otherwise wasteful uses. The City of Folsom's commitment to implementing these agreements should help maintain water use efficiency. Implementation of the CUWCC BMPs in the Folsom SPA will ensure that the Folsom SPA maintains the lower than historic indoor and outdoor unit demand factors identified in **Section 2.2** and **Section 6.1**.

2.2 FOLSOM SPA – PPA DEMAND FACTORS

2.2.1 Residential

Unit demand factors, used to estimate demand for the Folsom SPA-PPA, are developed by first estimating per capita use to generate an indoor unit demand factor and then landscaping demands are considered to develop an outdoor unit demand factor. The indoor and outdoor components are ultimately combined into a total unit demand factor for the residential land-use categories.

[34] CUWCC BMP 1.1(A) provides that a signatory shall designate a person as the agency's responsible conservation coordinator for program management. BMP 1.1(A) also requires a signatory to enact, enforce or support ... ordinances ... that (1) prohibit water waste ... and (2) address irrigation, landscape, and industrial, commercial, and other design inefficiencies.

[35] The City of Folsom's water waste ordinance is codified in Chapter 13.26 of the Folsom Municipal Code.

2.2.1.1 Indoor

In light of the discussion of various water use drivers in **Section 2.1.3**, unit demand factors for indoor residential land-use categories are estimated accordingly.

- Single-Family and Single-Family High Density: Based upon the meter study described in **Section 2.1.1**, the historic single-family indoor unit demand factor in the City's existing service area is approximately 0.22 af/du/yr. At 2.83 persons per household, the per capita demand is about 70 gallons per person per day (gpd).[36] If the City of Folsom adopts indoor water-efficient infrastructure policies similar to those suggested in **Section 2.1.3.2** to implement its water conservation targets adopted under SBX7 7, and implements metering and volumetric billing as described in **Section 2.1.3.4**, the historic indoor per capita unit demand factor will be reduced by at least ten percent (10%). Therefore, the single-family unit demand factor of 63 gpd is used to calculate the indoor water demand for the Folsom SPA - PPA.[37]

- Multi-Family Low Density; Multi-Family Medium Density; Multi-Family High Density; Multi-Use-Residential: The same per capita indoor unit demand factor is used for the multi-family units as is used for the single-family units because each person has similar individual indoor demands regardless of the size of the unit – e.g., bathing, dishwashing, clothes washing, toilet flushing.[38] Therefore 63 gpd is used as the indoor per capita unit demand for the multi-family and multi-use categories.

For the Folsom SPA - PPA, the indoor unit demand numbers for the single and multiple-family residential classifications are provided in **Table 2-4**. Using the dwelling unit population number for the Single-Family categories of 2.9 persons/unit and 1.9 persons/unit for the Multi-Family categories in combination with the per capita per day estimate of 63 gallons, the annual indoor unit demand factor is calculated as well.[39]

---

[36] See Table 2-2. [(.22af/du/yr)*(325851 gallons/af)/(2.83 persons/unit)/(365 days/yr)] The Folsom 2005 UWMP assumed 2.83 persons per household which is the per capita value that is used as the historical dwelling unit population density.

[37] For comparative purposes, EID has recorded indoor use values associated with projects in its El Dorado Hills service area that average about 60 gallons per person per day (see Appendix Table A, 2007 through 2009 Water Resources & Service Reliability Reports).

[38] The Folsom 2005 UWMP also assumed the multi-family indoor unit demand factor is the same as the single-family indoor unit demand factor.

[39] The dwelling unit population figure was calculated by dividing the estimated persons per unit by the total number of units for each land-use category as provided in **Appendix C**.

Table 2-4
Folsom SPA - PPA
Residential Unit Demands

Land Use	Capita per Household	Indoor gallons per capita / day	Indoor Unit Demand, AF/DU
SF	2.9	63	0.21
SFHD	2.9	63	0.21
MFLD	1.9	63	0.14
MFMD	1.9	63	0.14
MFHD	1.9	63	0.14
MU - Res	1.9	63	0.14

2.2.1.2 Outdoor

Review of historic City of Folsom data indicates a wide range of planning numbers for outdoor unit demand factors. As suggested in Section 2.2.1, based upon single-family meter data, outdoor usage in the residential sector is approximately 4.3 acre-feet/acre/ per year (af/ac/yr). An evapotranspiration-based turf demand was calculated in the Folsom Recycled Water Demand Technical Memorandum (TM) as 4.5 af/ac/yr.[40] The Folsom Recycled Water Demand TM also reviewed historic outdoor metered account usage and reported the average usage from 2000-2004 was 3.9 af/ac/yr. Thus, historic usage ranges between 3.9 – 4.5 af/ac/yr. While outdoor meters were only present in the non-residential sector when the unit demands were analyzed in the Recycled Water Demand TM, the unit demand factors from the non-residential sector provide an indication of historic outdoor unit demands in the residential sector given the general similarities in landscape design – specifically an emphasis on turf landscapes with accompanying plantings. Historic outdoor water use in the non-residential sector reflects a non-conservation based demand, as none of the City's parks or landscape and lighting accounts were implementing significant demand management measures at the time the Folsom Recycled Water Demand TM or 2005 UWMP was prepared. As explained below, post-2005 developments related to outdoor water demands support using outdoor unit demand factors for the Folsom SPA - PPA that are lower than the demands reflected in those two City documents.

[40] City of Folsom Recycled Water Demands Technical Memorandum. Brown and Caldwell, November 9, 2005.

The primary driver that could significantly change both residential and non-residential outdoor water demands is the MWELO. The MWELO provides that a landscape design plan should include plantings that use no more than seventy percent (70%) of reference evapotranspiration.[41] By requiring preparation of landscape plans for the Folsom SPA – PPA that use 70% of reference evapotranspiration, the long-term unit demand is likely to be somewhat greater than 70% ETo because of variations in plant and irrigation system maintenance. Therefore, this Folsom SPA – PPA demand estimate uses a "mid-point" between 100% ETo and that required in the MWELO - 85% of evapotranspiration, which is equivalent to 3.73 af/ac/yr. To achieve an outdoor unit demand of 3.73 af/ac/yr, consumptive demand would need to be approximately 2.6 af/ac/yr, assuming a 71% irrigation efficiency rate.[42] This would require an average plant factor of 0.6. The average plant factor could be higher if the efficiency rate were higher. For example, the plant factor could be 0.7 if the irrigation efficiency rate were at least 82%.

The outdoor unit demand factor of 3.73 af/ac/yr was developed based upon single-family lot size and associated landscape area for each lot in the Folsom SPA – PPA land-use plan. In the multi-family sector landscaped area is reflected as a percentage of total area for each multi-family category. The estimate of single-family lot area was made based upon the acreage and unit figures for the single-family land use categories as well as an estimate of the area necessary for roads and right-of-ways. For the Single-Family category, the planned unit density is three units per acre (1687 units/557.8 acres). If 25% of the area in the Single Family category is for roads and rights of ways, then the lot size is approximately 11,000 square feet (sf).[43] To estimate the landscaped area on each lot, the City of Folsom Zoning Code was used as a reference. Assuming the lots are 11,000 sf, they would likely have associated building standards similar to those in the City of Folsom's *Single Family Dwelling, Medium Lot District* category, which requires minimum 10,000 sf lots and maximum building coverage of 35%.[44] If 25% of the lot is used for hardscapes, then the remainder of the lot, as landscape area, would be approximately 40%.[45] For the Single-Family High Density Category, the planned unit density is approximately 5.5 units/acre (2933 units/532.5 acres). Again, using approximately 25% road and right-of-way dedication, then the average lot size would be

---

[41] CCR Title 23, Div. 2, Chapter 2.7, Sec. 492.4.
[42] See Footnote 20 for formula. ((53/(12*7.481))*.6*43560)/325851 = 2.65 af/ac.
[43] 25% was selected for roads and right of ways in a single-family neighborhood based on surveys of recently constructed subdivisions in the City of Folsom.
[44] City of Folsom Zoning Code, § 17.12.060.
[45] 25% was selected for hardscape coverage in the single-family categories based on surveys of recently constructed subdivisions in the City of Folsom.

about 6,000 sf. And, if some of the hardscapes in the Single-Family High Density category will occupy an area similar to that in the Single-Family category (e.g., a standard two-car driveway), then the Folsom SPA – PPA is assigned a landscaped area that is a smaller percentage of total lot area in the Single-Family High Density category – 30%.

For the Multi-Family categories in the Folsom SPA – PPA land-use plan, total area is first reduced by 10% to account for roads and right of ways.[46] Then landscaped area is derived by assessing that the building coverage is approximately 40-50% for the Multi-Family Low and Medium Density categories to 55% for the Multi-Family High Density category.[47] Since hardscapes are about 15-25% of lot area, then landscaped areas cover between 25-30% of the lot.[48] For the Multi-Unit Residential category, the landscaped area is only 10% of lot area because the combined commercial uses (in the Multi-Unit Nonresidential category) reduce landscaped areas with more area dedicated to hardscapes connecting the residential and commercial components. All residential land-use coverage assumptions for the Folsom SPA – PPA are provided in **Table 2-5.**

Table 2-5
Folsom SPA – PPA
Residential Land Use Coverage Assumptions

Land Use Category	Building Coverage (% of area)	Hardscape Coverage (% of area)	Landscape Coverage (% of area)
SF	35-40%	20-25%	40%
SFHD	35-40%	30-35%	30%
MFLD	40-50%	15-25%	25%
MFMD	40-50%	15-25%	25%
MFHD	50-55%	15-25%	30%
MU - Res	55-60%	25-30%	10%

[46] Because multi-family units tend to be accessed by main arterial roads and have limited interior roadways, 10% was selected as a reasonable figure across the multi-family categories. This accounts for those complexes accessed entirely by arterial roads, which are already accounted for in the Folsom SPA land-use data and provides for some internal roadways in condominium type complexes.

[47] Land coverage percentages were estimated based upon comparison to existing City of Folsom Zoning Code definitions. The existing R-2, Two-Family Residence definition provides for up to 40% lot coverage and the existing R-3, Neighborhood Apartment District definition provides for coverage up to 50%. It is assumed that the Folsom SPA - PPA Multi-Family Low and Medium Density categories are similar to the existing R-2 and R-3 definitions, thus the use of the 40-50% coverage range. For the Folsom SPA - PPA Multi-Family High Density category, it is assumed that this category is more like the City of Folsom's existing R-M, Residential Multi-Family Dwelling District definition which provides for the building to cover 60% of the lot. (See City of Folsom Zoning Code §§ 17.14, 17.16 and 17.17.)

[48] Hardscape area coverage assessed through electronic surveys of various multi-family complexes in the City of Folsom.

Table 2-6 shows the lot area and landscaped area numbers used to develop the outdoor unit demand factor for the residential categories in the Folsom SPA – PPA land-use plan. Consistent with the approach described in **Section 2.1.3.3**, the unit demand factor was developed by applying provisions of the MWELO to irrigated areas in the residential land-use categories. The long-term outdoor unit demand factor for the residential categories is calculated as a percentage of evapotranspiration. Specifically, as previously discussed in this section, unit demands are 85% of ETo. The product of the landscape area and the ETo factor is the outdoor unit demand factor.

Table 2-6
Folsom SPA - PPA
Residential Outdoor Demand Factors

Land Use	Lot Area, ft^2	Lot Landscape Area, ft^2	Landscape Area (Total), Acres	ETo Turf Irrig. Demand, inches/yr	ETAF	Outdoor Unit Demand, AFY/DU

2.2.2 Non-Residential

2.2.2.1 Non-Residential Land Use Coverage Percentages

The Non-Residential sector water demand for the Folsom SPA - PPA is evaluated on a land-area coverage basis. Each non-residential land-use is assigned an average coverage percentage for each non-residential land-use type – indoor, hardscape, and outdoor irrigation. Land-use coverage percentages were estimated based upon existing City land-use coverages as well as proposed Floor Area Ratios in the Commercial categories. First, for the Commercial categories, the Land Use Summary in **Appendix C** provides the target floor area ratios, which serve as an indicator of the "indoor" coverage percentage.[49] For this analysis, all commercial construction in the Community, General

[49] Because floor area may be comprised of building area on more than one story, the coverage percentage may be less than floor area, but without specific knowledge of the ultimate building design, the floor area serves as a reasonable approximation of the area that the building will cover.

and Regional Commercial categories is one story and the building footprint utilizes the maximum targeted floor area. For the Office Park category, some of the units have multiple stories and the indoor coverage percentage is reduced accordingly.[50]

Commercial: Generally, because the indoor coverage for the Commercial categories in the Folsom SPA - PPA is lower than the average historic figures used in the UWMP, coverage percentages for the hardscape and landscape categories are slightly higher than historic values. According to the Land Use Summary in **Appendix C**, in the Community, General and Regional Commercial categories, the floor area ratios are 25%, 25% and 28% respectively. Assuming equivalence between floor area ratio and indoor coverage, this is about 25-35% less than the indoor figures used in the 2005 UWMP. This "excess" indoor area was therefore assigned to the hardscape and landscape categories with about 15-20% to the landscape coverage and 10-15% to the hardscape coverage. While in some cases hardscape coverage is estimated to be as high as 45%, which is slightly higher than historic values, it is more consistent with recent trends towards maximizing parking and minimizing landscaping features.

For the Office Park category, **Appendix C** provides that target floor area ratio is 30%. Starting with this floor area ratio, a building coverage of 25% was estimated based on the previously stated assumption that some of the office park buildings will be more than one story. Again, because the floor area ratio is considerably less than the building coverage percentage assumed for the 2005 UWMP, the "excess" indoor area was assigned to the landscape category. Also, the hardscape coverage percentage was reduced from the 2005 UWMP value, with a percentage going to landscape coverage and also based on surveys of more modern office park complexes with a preference for significant landscape features.

Mixed Use: For the Mixed-Use Nonresidential category, the Land Use Summary in **Appendix C** indicates that the floor area ratio for the nonresidential component is 20%. Hardscape and landscape coverages are apportioned similar to Community Commercial, with slightly more landscape coverage in place of indoor coverage.

[50] While the City of Folsom Zoning Code (§ 17.22.050) would seem to provide for buildings in categories similar to the Commercial and Office Park categories for the Folsom SPA to have more than one story, it is not certain what type of businesses will ultimately be sited in the Office Park and Commercial categories. Therefore, the building area coverage estimate is driven primarily by windshield surveys by Tully & Young in new commercial and office park developments in the City of Folsom.

Schools: For the Schools category, Landscape coverage remains at 50%, consistent with historic values. Based upon an electronic map survey of the existing Folsom service area conducted by Tully & Young using Google Maps, indoor coverage was increased from the historic value of 10% to 25% and the hardscaped area is reduced accordingly to 25%.

Parks: For the Park and Local Park categories, minimal area is devoted to indoor uses and hardscapes. While these figures will vary depending on the location and purpose of the park space, on average, about 5% is devoted to the indoor and hardscape categories and 95% of the park space is landscaped.[51] This estimate provides a conservatively high demand total for the Park category because the landscape category has a higher unit demand factor than the indoor and hardscape categories.

Open Space and Circulation: As for the remaining two non-residential categories, natural non-irrigated landscape will comprise 100% of the Open Space category and so will create no project water demands. As for the Major Circulation category, 90% is dedicated to roads and 10% to irrigated medians and streetscapes.

All coverage percentages are provided in **Table 2-7**.

[51] Tully & Young assessed park coverage by using Google Maps to analyze parks in the City of Folsom.

2.2.2.2 Nonresidential Unit Water Demand Factors

Historic indoor unit water demand factors in the City's 2005 UWMP are revised, as explained in **Section 2.2.2.2**, to estimate baseline indoor unit water demands for the Folsom SPA – PPA. Working from the assumption that the City of Folsom must ultimately comply with the water conservation provisions of SBX7 7, which will require the City of Folsom to achieve 20% conservation relative to baseline use, historic non-residential indoor unit demands are conservatively reduced by 5%.[52] The Office Park and Regional Commercial Categories began with a baseline of 2 af/ac/yr, which was then reduced to 1.90 af/ac/yr. For the Community and General Commercial Categories, a common baseline of 1.75 af/ac/yr was used based upon averaging the historic Neighborhood and Regional Commercial categories in the UWMP. The baseline for the Community and General Commercial categories was also reduced by 5% to 1.66 af/ac/yr. The indoor baseline unit demand for Mixed Use – Nonresidential is assumed to be similar to Community Commercial – 1.75 af/ac/yr.

For the Schools categories, Tully & Young evaluated 2008 meter data for a mix of schools to determine whether the 2005 UWMP demand value of 3 af/ac/yr remains a reasonable average value. Based upon rough calculations of area and recent average annual water use, indoor water use was estimated to be about 2.6 af/ac/yr. Given the high degree of variability among the schools, the historic value of 3 af/ac/yr was retained as a conservative baseline. Similar to the Commercial categories, indoor unit demands were reduced by 5% to 2.85 af/ac/yr.

The landscape unit demand for all non-residential categories reflects the requirements of the MWELO as discussed in **Section 2.1.3**. Specifically unit demands are 85% of reference evapotranspiration (53 in.) Based upon review of recent meter data, reference evapotranspiration is a reasonable estimate of baseline landscape demand. Evaluation of recent park landscaping meter data indicates that average water use is about 4.3 af/ac/yr.[53] Approximately 85% of reference evapotranspiration is achieved both through the landscape design requirements in the MWELO as well as the irrigation design system requirements and recommendations for a weather-based controller and

[52] As explained in **Section 2.1.3.2.**, this WSA assumes that the nonresidential buildings and structures must comply with the water-efficient fixture requirements of the CAL Green Code. While the CAL Green Code water savings target is 20% compared to baseline use, this WSA assumes a 5% reduction in water use and adjustments to the indoor unit water demand factors are made accordingly.

[53] Tully & Young reviewed 2008 meter data for the City of Folsom's BT Collins, Cohn and Beach Hill Parks. The average 2008 unit demand was 4.2 acre-feet per acre.

dedicated irrigation meter. This is a conservative estimate appropriate for this planning stage.

A unit demand per acre is assigned for each coverage percentage as shown in **Table 2-7**.

2.3 Folsom SPA – PPA Non-Potable Water Demand

Currently, the City does not have a non-potable supply to serve any portion of the Folsom SPA. If non-potable water service is ultimately available, an indication of the scope of non-potable service may be found in the State Water Resources Control Board's *General Waste Discharge Requirements for Landscape Irrigation Uses of Municipal Recycled Water* (Recycled Water General Permit).[54] Under the Recycled Water General Permit, recycled water can be used in residential front or back yards if the municipality applies for, and obtains, an individual permit with the Regional Water Quality Control Board. According to the Recycled Water General Permit, specified uses of recycled water considered "landscape irrigation" projects include any of the following:

- Parks, greenbelts, and playgrounds;
- School yards;
- Athletic fields;
- Golf courses;
- Cemeteries;
- Residential landscaping, common areas;
- Commercial landscaping, except eating areas;
- Industrial landscaping, except eating areas; and
- Freeway, highway, and street landscaping.

If the City of Folsom were to require that the Folsom SPA - PPA demand categories corresponding to those eligible for non-potable service under the Recycled Water General Permit were to use non-potable water, then the land-use categories in **Table 2-8** would likely be eligible. The corresponding acreage and potential demand values are provided in **Table 2-8** as well.

[54] http://www.swrcb.ca.gov/water_issues/programs/water_recycling_policy/docs/wqo_2009_0006_general_permit.pdf. Non-potable supplies may be available in the future but they are not considered in this analysis.

Table 2-8[55]
Folsom SPA – PPA
Potential Non-Potable Water Demands

Land-Use Category	Landscape Acreage (AC)	Demand (AF/YR)
Parks	116	431
Streetscapes	17	64
C/I/O Landscape	147	549
Schools Landscape	90	334
Total	370	1379

2.4 PROJECTED WATER DEMANDS FOR FOLSOM SPA - PPA

Table 2-9 provides the annual water demands by land-use category for the Folsom SPA – PPA. The total estimated water demand for the Folsom SPA - PPA in a normal year is 5,422 AF, assuming a 10% non-revenue water factor.[56] In a dry-year, this total Folsom SPA - PPA demand is projected to increase to 5,577 acre-feet. The dry-year increase is a result of increasing the normal year outdoor demand for all residential and non-residential demand categories by 5% and then applying the non-revenue water factor of 10%.[57] The 5% increase is applied to the annual outdoor demand factor of 3.73 acre-feet/acre/year.

The portion of the Folsom SPA - PPA that is within the EID service area is projected to have a water demand of 255 AF in a normal year and 262 AF in a dry year, as shown in **Table 2-9**. Finally, **Table 2-9** also provides an indication of the balance between indoor and outdoor water demands for all land-use categories in both the Folsom and EID service areas.

---

[55] The demand estimates are based on the outdoor unit demand factor of 3.73 acre-feet/acre/year as developed in Section 2.2.1.2. This is a conservatively high value when compared to recorded demand factors documented by EID in its annual Water Resources & Services Reliability Reports, which reported unit demands to be less than 3.0 acre-feet/acre/year. This conservatively high value is further supported, using the evapotranspiration data from a local weather station and comparing high and low values over the last 12 years. Based on the data the highest yearly value (representing the hottest year) is only 5% higher than the average for the period of record.

[56] As a signatory to the CUWCC MOU, the City of Folsom is committed, pursuant to BMP 1.2(f), to following American Water Works Association standards for system water audits, leak detection and repair. It is also committed to achieving non-revenue water losses no greater than 10% of total water introduced into its system (i.e., supply entering the treatment plant). Because the demand for the Folsom SPA-PPA is calculated from the end-user perspective, reflecting a 10% non-revenue water loss of the water entering the treatment plant translates to an equivalent of 11.11% of end-user demand. Thus, 5,422 AF/YR is the result of adding 11.11% to the end-user demand estimate.

[57] Outdoor demand is increased by 5 percent in dry years because a dry winter tends to motivate customers to begin irrigation sooner in the season.

SECTION 3 FOLSOM SPA WATER SUPPLY

3.1 EXPLANATION OF THE PROPOSED WATER SUPPLY

Section 3 provides an explanation of the water supply that the City of Folsom will use to serve the Folsom SPA. [58] The City will meet the Folsom SPA water demands by securing an assignment of a Sacramento River surface water supply from the Natomas Central Mutual Water Company (NCMWC) pursuant to NCMWC's CVP settlement contract with the United States Bureau of Reclamation (USBR).[59] The water supply to be assigned is a long-term "Project Water" supply.[60] An initial purchase and sale agreement between South Folsom Properties LLC (SFP) and NCMWC is in place and identifies the conditions which ultimately need to be satisfied by both parties to finalize the sale, which will ultimately lead to an assignment to the City.

Currently, NCWMC diverts water and conveys it to its shareholders that apply water to agricultural lands in northern Sacramento County and southern Sutter County. NCMWC's contract provides for delivery of Project Water on an agricultural schedule, with the Project Water delivered during the late irrigation season in the months of July and August. The City will seek modification of the Project Water delivery schedule from the USBR such that water may be delivered to the City on a year-round municipal and industrial (M&I) schedule.[61] The City will divert the assigned Project Water at the Freeport Regional Water Authority's Freeport diversion facility on the Sacramento River

[58] CWC § 10910 (d) (1) requires that "The assessment ... include an identification of any existing water supply entitlements, water rights, or water service contracts relevant to the identified water supply for the proposed project, and a description of the quantities of water received in prior years by the public water system, or the city or county if either is required to comply with this part pursuant to subdivision (b), under the existing water supply entitlements, water rights, or water service contracts. (2) An identification of existing water supply entitlements, water rights, or water service contracts held by the public water system, or the city or county if either is required to comply with this part pursuant to subdivision (b), shall be demonstrated by providing information related to all of the following: (A) Written contracts or other proof of entitlement to an identified water supply. (B) Copies of a capital outlay program for financing the delivery of a water supply that has been adopted by the public water system. (C) Federal, state, and local permits for construction of necessary infrastructure associated with delivering the water supply. (D) Any necessary regulatory approvals that are required in order to be able to convey or deliver the water supply."

[59] Contract No. 14-06-200-885A-R-1.

[60] "Project Water" is "... all surface water diverted ... each month during the period April through October ... from the Sacramento River which is in excess of Base Supply." "Base Supply" is "... the quantity of surface water ... which may be diverted ... from the Sacramento River each month during the period April through October of each year without payment to the United States for such quantities diverted." Article 1 of the 2005 Contract Between the United States and the Natomas Central Mutual Water Company (Renewal Contract), which is included in **Appendix G**

[61] A M&I schedule is generally one with the highest daily demands during the height of the outdoor irrigation season and lower daily demands in the spring and fall and even lower daily demands throughout the winter.

in southern Sacramento County.[62] Water will be conveyed from the Freeport diversion facility to the Folsom SPA via both FRWA facilities, which are already under construction, as well as facilities that will be constructed by the City of Folsom. The water may be either treated by SCWA or the City of Folsom pending further review of various conveyance and treatment alternatives.[63]

As explained in **Section 3.4**, the City of Folsom and the Sacramento County Water Agency (SCWA) have approved the *Memorandum of Understanding Between the City of Folsom and Sacramento County Water Agency Concerning the Folsom Sphere of Influence Area and Sharing of Freeport Project Capacity* (City - SCWA MOU). The City – SCWA MOU commits each party to try to find a mutually agreeable solution to the issue of system capacity in the FRWA facilities so that the City of Folsom can use some of that capacity to deliver Sacramento River water to the Folsom SPA. The water supply that will derive from the NCMWC assignment and be delivered under an agreement following the City – SCWA MOU will be used in both Folsom's and EID's service areas within the Folsom SPA.

The use of this water supply does not impact either the City's or EID's existing water supplies or conveyance facilities. Through SFP, the City intends to acquire water from NCMWC to serve only the Folsom SPA. Water treatment will occur at either newly constructed facilities that will not be connected to the City of Folsom's or EID's existing treatment and conveyance facilities or at third parties' treatment facilities. Thus, neither the water demands associated with land uses in the City of Folsom exclusive of the Folsom SPA, nor the water supplies used to serve these areas, are analyzed in this Folsom SPA WSA.

3.2 Surface Supply Analysis

3.2.1 NCMWC Water Supplies

Surface water will be obtained from the NCWMC pursuant to a series of agreements. Initial agreements include one between SFP and NCMWC, and the second between SFP and the City of Folsom. The agreement between SFP and the NCMWC has been

[62] The Freeport Regional Water Authority (FRWA) was created by a Joint Powers Agreement between the Sacramento County Water Agency (SCWA) and East Bay Municipal Utility District (EBMUD). FRWA guides the financing, ownership, development, construction, and operation of the Freeport Regional Water Project (FRWP). The FRWA Board of Directors is made up of two representatives from SCWA, and two representatives from EBMUD. The City of Sacramento is an Associate Member of FRWA.

[63] Conveyance alternatives are analyzed in the Draft EIR/EIS.

executed.[64] The City of Folsom and SFP have executed a non-binding memorandum of understanding.[65] The City and SFP cannot sign a binding legal agreement until after the environmental review – of which this WSA is a part – is completed. The ultimate goal is to complete an assignment of a portion of NCMWC's Project Water supply to the City of Folsom.[66] NCMWC's CVP settlement contract contemplates such an assignment.

NCMWC entered into Contract No. 14-06-200-885A (Settlement Contract) with the USBR in 1964. The Settlement Contract is based on NCMWC's pre-existing licenses and permit to divert water. The Settlement Contract provides for delivery of water to NCMWC during the months of April through October. Effective on May 10, 2005, the Settlement Contract was renewed for a 40-year term (Renewal Contract).

Under the Renewal Contract, in addition to its Base Supply, NCMWC is entitled to divert up to 22,000 acre-feet of "Project Water" which is available during July and August. Distribution of NCMWC's monthly diversion entitlements for Project Water is shown in **Table 3-1**. The Renewal Contract limits NCMWC's annual diversions of water from the Sacramento River to the total quantities included in its Base and Project Supplies regardless of the entitlement pursuant to which the water is diverted.[67]

Table 3-1

Project Water Supply Allocation

Month	Project Water Supply (af)
April	0
May	0
June	0
July	7,200
August	14,800
September	0
October	0
Total	**22,000**

[64] On December 17, 2007, SFP and NCMWC entered into an agreement entitled *Terms and Conditions of Purchase and Sale of Water Entitlements*. (SFP-NCMWC Agreement) A copy of the SFP-NCMWC Agreement is included as **Appendix E.**
[65] A copy of the City-SFP MOU is attached as **Appendix F**.
[66] Assignments are allowed under Article 23 of the 2005 Contract Between the United States and the Natomas Central Mutual Water Company (Renewal Contract), which is included in **Appendix G**.
[67] NCMWC's Base Supply is not a water source for the City and is not considered in this WSA.

3.2.1.1 Reliability of NCMWC Surface Water Supplies

Annual water deliveries to the NCMWC from the USBR pursuant to the Renewal Contract are determined on the basis of natural inflow to Shasta Lake (the Shasta Index). In a normal year when there is ample water in the Central Valley Project (CVP) system, NCMWC receives 100% of its Renewal Contract entitlement. The maximum reduction in NCMWC's diversions during any "Critical Year" is 25% of both Base Supplies and Project Water.[68] A "Critical Year" means any year in which either of the following conditions exist:

(1) The forecasted full natural inflow to Shasta Lake for the current Water Year (October 1 through September 30), as such forecast is made by the United States on or before February 15 and reviewed as frequently thereafter as conditions and information warrant, is equal to or less than 3.2 million acre-feet; or

(2) The total accumulated actual deficiencies below 4 million acre-feet in the immediately prior Water Year or series of successive prior Water Years each of which had inflows of less than 4 million acre-feet, together with the forecasted deficiency for the current Water Year, exceed 800,000 acre-feet.

"Critical Years" occur relatively infrequently. Over 85 years of record (1921-2006), a Shasta Index "Critical Year" would have been triggered only nine times (1924, 1931, 1932, 1933, 1934, 1977, 1991, 1992, and 1994).[69] This results in the occurrence of a "Critical Year" less than once every nine years.

Table 3-2 provides the "Critical Year" water allocation assumption for the NCMWC Project Water supply. As shown, during a "Critical Year," NCMWC receives no less than 75% of its normal year Project Water entitlement, or 16,500 acre-feet.

[68] Article 5(a), Renewal Contract. Article 5(a) is the exclusive provision governing dry-year reductions of NCMWC's water supplies under the Renewal Contract. USBR's draft *2001 M&I Shortage Policy*, if implemented, will not apply to the NCMWC water supply because NCMWC is a settlement contractor, and its Renewal Contract therefore specifically defines the maximum reductions.

[69] www.usbr.gov 8/28/09

Table 3-2
NCMWC "Critical Year" Project Water Supply

Month	Project Water Supply (af)
April	0
May	0
June	0
July	5,400
August	11,100
September	0
October	0
Total	**16,500**

NCMWC's Renewal Contract, among many other Central Valley Project contracts, was challenged in *Natural Resources Defense Council v. Kempthorne*, Case No. 05-CV-01207 (E.D. Cal). In that case, the Honorable Oliver Wanger of the U.S. District Court for the Eastern District of California, upheld NCMWC's Renewal Contract. His decision has been appealed to the federal Court of Appeals for the Ninth Circuit. In certain orders, Judge Wanger ruled that the supply of "Project Water" under NCMWC's Renewal Contract could be reduced "to meet legal obligations" of USBR. If these orders were to be read conservatively, then they would impose on USBR, at most, a contractual obligation to comply with applicable laws, which is a standard element of most contracts. (See e.g., *Edwards v. Arthur Andersen LLC* (2008) 44 Cal.4th 937, 954.) These orders therefore do not adversely affect "Project Water" supplies under NCMWC's Renewal Contract for purposes of this WSA, any more than application of standard contract-law principles would. Because Judge Wanger upheld the Renewal Contract on the basis that USBR had no discretion to reduce NCMWC's water supplies in executing the Renewal Contract, the judge's "legal obligations" rulings probably will have less effect than would be indicated by the above conservative interpretation.

3.2.1.2 Modifications to the NCMWC Delivery Schedule

Tables 3-1 and 3-2 show the NCMWC's existing water delivery patterns in normal and critical years under its existing Renewal Contract with USBR. For the Project Water supply to serve as an effective water supply for the Folsom SPA, it will be necessary to obtain USBR approval for a modification to the delivery schedule to satisfy Folsom SPA demands on a traditional M&I pattern throughout the calendar year. According to the

Folsom SPA Notice of Preparation, "the City will work with Reclamation [USBR] or another CVP contractor to reschedule the delivery of the assigned Project Water Supply."

Table 3-3 provides an example of the delivery pattern that the City intends to seek for delivery of 5,577 AF over a twelve month period under the Folsom SPA – PPA land-use plan.[70] For planning purposes, not only does **Table 3-3** reflect the potential demand pattern, it addresses the potential capacity requirements in the FRWA and the proposed Folsom conveyance systems by providing monthly and annual average day demand, and maximum day demand. Because the maximum day demand may occur at any time throughout the year, maximum day demand is estimated by multiplying annual average day demand by 1.9.

Table 3-3
Demand Pattern for the Folsom SPA - PPA

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Pattern (% Total)	4.4%	3.9%	5.5%	6.5%	9.3%	11.5%	14.1%	13.5%	11.8%	9.1%	5.5%	4.7%

Maximum Day (Ann. Avg. Day x 1.9) (MG)													9.5

3.3 Agreements Supporting A Plan to Secure A Water Supply[71]

3.3.1 NCMWC – South Folsom Properties Agreement

Under the SFP-NCMWC Agreement, NCMWC agreed to permanently assign to the City, through SFP, not less than 8,000 acre-feet per year (AF/YR) of "Project Water" to which NCMWC has rights under the Renewal Contract. NCMWC did not exercise its option under Section 3.2 of the SFP-NCMWC Agreement to increase the amount of water from the initial amount of 8,000 AF/YR to be purchased by SFP, and therefore the total water supply to be assigned to the City of Folsom by NCMWC is 8,000 AF/YR. The SFP-NCMWC Agreement provides that the assigned water will be subject to a 25% reduction in a "Critical Year."(See discussion of "Critical Year" supply reductions in **Section 3.2.1.1** above.)

[70] Demand pattern obtained from analysis of the Historic Folsom Water Treatment Plan Flows prepared by the J. Crowley Group, December 2007.
[71] The agreements described in **Section 3.3** are intended to satisfy the requirement in CWC § 10910(d)(2)(A) to provide "Written contracts or other proof of entitlement to an identified water supply."

The SFP-NCMWC Agreement is effective until April 1, 2012, unless extended by SFP. Under that agreement, SFP may extend its term for up to five additional one-year periods. During the period that the SFP-NCMWC Agreement is effective, both NCMWC and SFP must satisfy specific obligations to ensure that water can ultimately be made available for use as a municipal and industrial supply in the Folsom SPA. Those obligations include, but are not limited to (1) preparation of an engineering study to ensure NCMWC may meet its future demands in the absence of the assigned supply; (2) approval from USBR to reschedule the assigned supply from an irrigation demand schedule to a municipal and industrial demand schedule; and (3) completion of all state and federal environmental review.[72]

3.3.2 City - South Folsom Area Group Agreement

On August 26, 2008, the City and SFP signed a memorandum of understanding that contemplates that SFP will assign the supply that SFP is acquiring under the SFP-NCMWC Agreement (Natomas Water) to the City for use as a new water supply for the Folsom SPA upon the completion of all legal requirements.[73] Specifically, the MOU contemplates that the City will evaluate the technical feasibility of delivering water on a year-round municipal and industrial pattern, diverting water from the Sacramento River at the FRWA facilities, and conveying water to the Folsom SPA using FRWA facilities. The MOU also contemplates that the City will identify alternatives identified in **Section 3.5** for conveying and treating Natomas Water.

3.4 Capacity Agreement

The City of Folsom and SCWA approved a City - SCWA MOU.[74] The purpose of this MOU is to establish principles and parameters to govern negotiations between the parties for City's purchase of a portion of the SCWA's capacity in the FRWA facilities in order to convey Natomas Water to supply the area encompassed by the SOI. The City – SCWA MOU indicates that the City and SCWA will cooperate during the MOU's term to develop conditions under which the City may convey the Natomas Water using SCWA's FRWA capacity, with the common goal of eventually executing a binding agreement (City-SCWA Agreement). The City – SCWA MOU therefore acknowledges that the average daily capacity in the FRWA facilities that would be available for purchase by the City is 6.5 mgd with consideration of an appropriate peaking factor.

[72] Specifically, SFP, in cooperation with the City, is to be responsible for obtaining all necessary approvals from USBR, including the scheduling approval and environmental review processes. Also, the City is to serve as the lead agency under CEQA and USBR will perform all duties under NEPA and the ESA. (See Sections 16 and 17 of the SFP-NCMWC Agreement.)

[73] See Appendix F.

[74] A copy is attached as **Appendix H.**

3.5 CONVEYANCE ALTERNATIVES

As for conveyance from the FRWA facilities, there are numerous routing alternatives considered in the Draft EIR/EIS:

Alternative 1 and 1A: Convey raw water from the FRWA Bifurcation to the Folsom SPA along Grant Line Road for the majority of the route with two potential approaches to the proposed Folsom Water Treatment Plant (WTP);

Alternative 2, 2A and 2B: Use the proposed SCWA Vineyard WTP to treat water and then convey to Florin Road, then north along either Excelsior or Eagles Nest Road to Douglas, then east to Grant Line Road, and north to the Folsom SPA;

Alternative 3 and 3A: Convey raw water from the FRWA Bifurcation to Florin Road, then north along either Excelsior or Eagles Nest Road to Douglas, then east to Grant Line Road, and north to the Folsom WTP at the Folsom SPA; and

Alternative 4 and 4A: Convey raw water from the FRWA Bifurcation north along either Excelsior or Eagles Nest Road to a proposed Folsom WTP on Folsom Boulevard, and ultimate conveyance to the Folsom SPA after treatment at the Folsom Boulevard location.[75]

No USACE Permit Off-site Water Facility Alternative: Convey raw water through the conveyance pipeline under Alternatives 1 and 3 above but would have no impact to waters of the United States.

The necessary easements and permits will need to be secured once an alternative is selected. Ultimately, the conveyance alternative selected will accommodate the supply secured from NCMWC.

3.6 FACILITIES COST AND FINANCING

3.6.1 Facility Costs

The Draft Project Facilities Financing Plan (PFFP) focuses on the costs of backbone infrastructure and community facilities for the Folsom SPA as well as the financing of these facilities. The Draft PFFP specifically addresses water infrastructure costs and

[75] A set of maps identifying the water conveyance alternatives is attached as **Appendix I.**

financing.[76] Because the scope of the current water infrastructure requirements and the associated cost estimates are comprehensive, the Draft PFFP provides considerable support for the City of Folsom's plan to secure a reliable water supply for the Folsom SPA. It is anticipated that the cost projections and financing strategies will be refined throughout the planning process.

Anticipated potable water improvements included in the Draft PFFP are an off-site transmission main, an on-site water treatment plant, storage tanks, booster stations, distribution mains, and laterals. Additionally, the Draft PFFP includes the cost associated with the City of Folsom acquiring conveyance capacity in the FRWA facilities. Taken together, by acquiring capacity in the FRWA system, and constructing the proposed City of Folsom conveyance, treatment and storage facilities, it will be possible to deliver the NCMWC supply to the Folsom SPA.

Complementing the potable water system, the Draft PFFP includes a recycled water system in the Project's initial design objectives and policies. To this end, the Draft PFFP includes a cost estimate for non-potable water deliveries. Yet, because the City does not have non-potable supplies available at this time, non-potable supplies are not considered to be available for purposes of estimating supply sufficiency in the WSA.

The gross cost estimate for potable and non-potable water facilities is approximately \$302.1 million. However, because the cost of the water supply (\$32 million) is to be funded with revenue bond proceeds and approximately 48% (based on City staff's estimate) of the water treatment plant costs relate to projects outside the plan area, the total net cost for potable and non-potable water facilities is estimated to be \$245.8 million.[77]

With a net project-specific cost totaling \$245.8 million, one-time burdens vary from \$6,301 per central commercial mixed use unit to \$38,882 per single family unit. Non-residential land use designations, meanwhile, are assigned a cost per acre ranging from \$80,331 per regional commercial acre to \$113,378 per office park acre.[78]

[76] The Draft PFFP assesses public facility feasibility based upon the land uses in the Folsom Plan Area Specific Plan, Administrative Review Draft, June 6, 2008. A discussion of the Draft PFFP is included in **Section 3.6** to satisfy the requirement to submit information regarding a capital outlay program to demonstrate entitlement to the identified water supply pursuant to CWC § 10910(d)(2)(B).
[77] Draft PFFP, p. 13.
[78] Draft PFFP, p. 18.

3.6.2 Financing Plan

The Draft PFFP identifies the basic components of the financing plan. Specifically, the plan includes development impact fees, utility revenue bonds, debt issued through the Mello-Roos Community Facilities Act, and developer capital.[79] If a Community Facilities District (CFD) is formed, special taxes will be collected to repay the bonds issued by the CFD. Also, an additional monthly charge included on property owners' utility bills will be collected to repay the utility revenue bonds.

Developer impact fees will fund the total net project-specific costs. A project-specific fee will ensure allocation of backbone and community facility costs among properties in the plan area.[80] The project applicant has proposed the use of revenue bonds to fund the anticipated cost to acquire rights to water supplies, and without revenue bonds, it would be necessary to increase developer impact fees. The Draft PFFP recommends establishment of a Mello-Roos CFD and issuance of tax-exempt bonds. The Draft PFFP earmarks special taxes for the public facilities to maximize available [bond] capacity. In total, $288.3 million in net CFD proceeds are expected to be generated through bonding.[81] Finally, the Draft PFFP assumes that developer capital will be required to close gaps between the time infrastructure is needed and revenues become available through the developer impact fees, utility revenue bonds and Mello-Roos CFD mechanisms.

3.7 Regulatory Approvals and Permits

Pursuant to CWC § 10910(d)(2)(C)-(D), the City shall identify, for its proposed water supply: (1) Federal, state, and local permits for construction of necessary infrastructure associated with delivering the water supply; and (2) Any necessary regulatory approvals that are required in order to be able to convey or deliver the water supply. The anticipated federal, state and local permits are identified in the Draft EIR/EIS.[82] Based upon the ultimate quantity of water assigned, the capacity agreement with SCWA, the conveyance route selected and the treatment process chosen, the City of Folsom will obtain the appropriate approvals and permits from the suite listed in **Appendix J**.

3.8 Proof of Appropriation

CWC § 10910(e) requires that, if the water supplier has not received water from the designated source before, then the WSA has to contain "an identification" of the other

[79] Draft PFFP, p. 24.
[80] Draft PFFP, p. 24.
[81] Draft PFFP, p. 25.
[82] Draft EIR/EIS, Section 1.6.3. A copy of Section 1.6.3 is attached as **Appendix J**.

water suppliers "that receive a water supply or have existing water supply entitlements . . . or water service contracts, to the same source of water as the public water system . . . has identified as a source of water supply within its [WSA]." The City of Folsom has not previously received a water supply from either the NCMWC or the Sacramento River. The source of water from which the City will obtain its supplies is NCMWC's unique Renewal Contract, which is based on NCMWC's unique underlying water rights. The NCMWC has been entitled to divert Project Water under the Renewal Contract consistently since the contract took effect in 2005. Upon assignment, the City should be entitled to divert Project Water as well in a manner similar to that provided for under NCMWC's Renewal Contract, with an adjustment in the water delivery schedule to reflect the Folsom SPA's municipal and industrial demand pattern.

3.9 Supply Summary

Based upon the City of Folsom's plan to ultimately secure an assignment of a portion of NCMWC's Project Water supply, the normal year supply contractually available for the City of Folsom under the assignment is 8,000 AF/YR. The maximum diversion for the Folsom SPA will be 6,000 AF/YR. The existing agreement between SFP and NCMWC, and the existing non-binding memorandum of understanding between SFP and the City, provides the foundation for the City to obtain an entitlement to the water supply through an assignment approved by USBR. Consistent with the dry-year shortage provisions in the Renewal Contract, the supply ultimately assigned to the City of Folsom will be subject to a 25% reduction in "Critical Years." For purposes of the sufficiency analysis in **Section 4**, this reduction results in 6,000 AF being available in both single and multiple-dry year conditions.

In addition to the water supply agreements that have been signed, the City of Folsom is diligently pursuing conveyance and treatment options to use the supply to be assigned by NCMWC with specific focus on acquiring and using capacity in the FRWA facilities, which are already permitted and partially constructed. Moreover, the Draft PFFP provides cost estimates for the water supply and treatment infrastructure necessary to serve the Folsom SPA with the supply to be assigned by NCMWC. Given these efforts to date, the City of Folsom has a viable plan for a secure supply for the Folsom SPA.

SECTION 4 FOLSOM SPA – PPA SUPPLY SUFFICIENCY ANALYSIS

Section 4 provides analysis of the sufficiency of the designated water supply for the projected Folsom SPA – PPA water demands.[83] **Table 4-1** incorporates the demand projection in **Table 2-10**, including both normal and dry-year demand projections at 2033. It also contains the supply projections discussed in **Section 3**. Although 8,000 AF/YR is anticipated to be available to the City of Folsom under the assignment, for every normal water year between 2013 and 2033, the City will divert a maximum of 6,000 AF/YR to serve the Folsom SPA. For each single and multiple-dry year period, it is assumed that the 8,000 AF/YR base water supply is restricted pursuant to the "Shasta Critical" provisions discussed in **Section 3.2.1.1**, thereby reducing the base supply by 25% and resulting in a total supply of 6,000 AF.

Conveyance water infrastructure is expected to be complete by 2013 in time to make water deliveries to the project. Given the limited development anticipated in 2013, there will be a significant surplus of water. In a dry year at full project build out anticipated to be in 2033, supplies are still estimated to exceed demand by about 425 AF/YR because annual dry-year demand will be approximately 5,577 AF/YR and supplies will be approximately 6,000 AF/YR. Thus, based upon the information in **Table 4-1** and the supporting analyses in **Sections 1** through **3**, the Folsom SPA - PPA will have a sufficient water supply at full project buildout, even in single and multiple dry year periods.

Table 4-1
Folsom SPA – PPA
Supply/Demand Comparison

Year	Projected Baseline Water Demand (ac-ft/year)	Surface Water			Projected Surplus/ (Shortfall) (ac-ft/year)
		Hydrologic Year Type		Available Water Supply (ac-ft/year)	
2033	5,421	**Normal**		6,000	579
	5,577	**Single Dry**		6,000	423
		Multiple Dry	Year 1	6,000	423
			Year 2	6,000	423
			Year 3	6,000	423

[83] CWC § 10910 (c)(4) provides that "If the city or county is required to comply with this part pursuant to subdivision (b), the water supply assessment for the project shall include a discussion with regard to whether the total projected water supplies, determined to be available by the city or county for the project during normal, single dry, and multiple dry water years during a 20-year projection, will meet the projected water demand associated with the proposed project, in addition to existing and planned future uses, including agricultural and manufacturing uses."

SECTION 5 FOLSOM SPA – RHA LAND USE PLAN

5.1 LAND USE PLAN CHARACTERISTICS

The Folsom SPA - RHA land uses are provided in **Table 5-1**. The land uses are depicted graphically in **Appendix K.**[84] Total project acreage will be 3,502 acres, including 11,553 dwelling units. As discussed in the Introduction, the Folsom SPA-RHA is not the proposed project to be analyzed under CWC §§ 10910(a) and 10912(a), but rather is analyzed in this WSA because the EIR/EIS analyzes the Folsom SPA-RHA at the level of detail required by NEPA and the Folsom SPA-RHA contains more residential units than the Folsom SPA-PPA.

SECTION 6 FOLSOM SPA – RHA WATER DEMAND ESTIMATE

Section 6 provides a water demand projection for the Folsom SPA - RHA.[85] The demand projection in **Section 6** uses the bases for the unit demand factors for the Folsom SPA - PPA outlined in **Section 2.1**. Both the historic demand factor assessment and the conservation drivers provide a foundation for the water demand projection in **Section 6.1**. **Section 6.2** identifies potential demands that could be served by a non-potable supply. **Section 6.3** provides the water demand projection used for the sufficiency analysis in **Section 8**.

6.1 FOLSOM SPA – RHA DEMAND FACTORS

6.1.1 Residential

The residential unit demand factors for the Folsom SPA - RHA include both an indoor and outdoor component. The indoor unit demand factor for both the single-family and multi-family residential categories remains the same as that used for the Folsom SPA – PPA as described in **Section 2.2.1.1**. Given the difference in the proposed unit densities for the Folsom SPA - RHA, unique residential outdoor unit demand factors were developed. The indoor and outdoor components are ultimately combined into a total unit demand factor for the residential land-use categories.

6.1.1.1 Indoor

For the Folsom SPA - RHA, the indoor unit demand factors for the single and multi-family residential classifications are provided in **Table 6-1**. Assuming the housing product type and the number of persons per unit is the same as the Folsom SPA - PPA for each land use classification, the indoor unit demand factors for the Folsom SPA – RHA are the same for each residential category.

[85] CWC § 10910(c)(4) provides that "If the city or county is required to comply with this part pursuant to subdivision (b), the water supply assessment for the project shall include a discussion with regard to whether the total projected water supplies, determined to be available by the city or county for the project during normal, single dry, and multiple dry water years during a 20-year projection, will meet the projected water demand associated with the proposed project, in addition to existing and planned future uses, including agricultural and manufacturing uses."

Table 6-1
Folsom SPA - RHA
Residential Unit Demands

Land Use	Capita per Household	Indoor gallons per capita / day	Indoor Unit Demand, AF/DU
SF	2.9	63	0.21
SFHD	2.9	63	0.21
MFLD	1.9	63	0.14
MFMD	1.9	63	0.14
MFHD	1.9	63	0.14
MU - Res	1.9	63	0.14

6.1.1.2 Outdoor

For the Folsom SPA - RHA, outdoor unit demand factors are projected to be higher than the Folsom SPA - PPA because the unit density for each residential land use category is lower. (Compare **Table 1-1** and **Table 5-1**.) Assuming each buildable acre has approximately 25% of the area devoted to roads and approximately 75% of the area for the lots, the area of the Single Family lots is assumed to increase from 11,000 square feet (sq. ft.) to 12,373 sq. ft., and the Single Family High Density lot area is assumed to increase from 6,000 sq. ft. to 6,749 sq. ft. A percentage of the difference in lot area for each category is assigned to both landscape coverage and hardscape coverage. For the Folsom SPA - RHA, 50% of the difference in lot area for the Single Family categories is assigned to landscape coverage for each category as shown in **Table 6-2**, and 50% is assigned to hardscape coverage.

By assigning 50% of the additional lot area in each Single-Family category to landscape area, unique landscape area totals were developed for each lot type as well as unique landscape area coverage percentages. Assuming the building size remains the same, then the original building coverage area remains the same and the hardscape area is adjusted accordingly to fill the remainder of the area not occupied by the building or landscape area.

Table 6-2
Folsom SPA - RHA
Building Acreage Assignment Assumptions[86]

Land Use Category	Assignment Percentages for Additional Residential Lot Area
SF	50% of difference to landscape
SFHD	50% of difference to landscape
MFLD	30% to landscape (up by 3.0%)
MFMD	30% to landscape (up by 3.0%)
MFHD	No Change
MU - Res	30% to landcape (up by 3.0%)

For the Multi-Family Low Density and Multi-Family Medium Density categories, 30% of the additional lot area is assigned to landscape area thereby increasing landscape coverage from 25% to 28%. For the Multi-Family High Density category, the layout may change most significantly with the possibility of fewer multi-level structures, thereby leading to similar building, landscape and hardscape coverages as those assumed in the Folsom SPA - PPA. For the Multi-Use Residential category, the landscape coverage is increased from 25% to 28% as well, under the assumption that more area than originally planned may be devoted to hardscapes that connect with the adjacent Multi-Use Nonresidential land uses (i.e., commercial uses). The land area coverage assumptions for the Folsom SPA – RHA are shown in **Table 6-3**.

Table 6-3
Folsom SPA - RHA
Residential Land Use Coverage

Land Use Category	Building Coverage (% of area)	Hardscape Coverage (% of area)	Landscape Coverage (% of area)
SF	36%	23%	41%
SFHD	36%	32%	32%
MFLD	47%	25%	28%
MFMD	47%	25%	28%
MFHD	55%	15%	30%
MU - Res	57%	30%	13%

[86] The remaining percentage under each land use coverage classification is assigned to hardscape, which has a demand factor of zero.

The increase in landscape coverage results in a higher outdoor unit demand factor than the Folsom SPA-PPA for each residential land classification. Consistent with the approach described in **Section 2.1.3.3**, the long-term outdoor unit demand factor for the single-family residential categories is calculated as a percentage of evapotranspiration. The landscape coverage has a demand per acre similar to that calculated for the Folsom SPA - PPA – 3.73 af/ac. The unit demand factor for each classification is provided in **Table 6-4**.

Table 6-4
Folsom SPA - RHA
Residential Outdoor Demand Factors

Land Use	Lot Area, ft^2	Lot Landscape Area, ft^2	Landscape Area (Total), Acres	ETo Turf Irrig. Demand, Inches/yr	ETAF	Outdoor Unit Demand AFY/DU
SF	12,373	5,087	n/a	53	85%	0.44
SFHD	6,749	2,175	n/a	53	85%	0.19
MFLD	n/a	n/a	122	53	85%	0.12
MFMD	n/a	n/a	36	53	85%	0.06
MFHD	n/a	n/a	29	53	85%	0.05
MU - Res	n/a	n/a	3	53	85%	0.02

6.1.2 Non-Residential Unit Demand Factors

6.1.2.1 Non-Residential Land Use Coverage Percentages

The Folsom SPA – RHA non-residential sector unit demand factors are based on land-use coverage area. With one exception, each non-residential land-use coverage area percentage is assumed to be same as that used for the Folsom SPA - PPA. (See **Section 2.2.2.1.**) For school property, 50 percent of the landscape area will include non-irrigated areas based on some of the areas that are traditionally landscaped are instead hardscaped. The non-residential landscape area coverage percentages are shown in **Table 6-5**.

Table 6-5
Folsom SPA - RHA
Non-Residential Unit Demand Factors

Land-use Category	Acres	Use Class	Coverage %	Use Class Unit Demand (AF/AC/YR)	Land Use Unit Demand (AF/AC/YR)

		Landscape (Irr.)	10%	3.29	0.33
		Total	100%		0.33

6.1.2.1 Nonresidential Unit Water Demand Factors

Nonresidential demand factors for the Folsom SPA - RHA were derived in a manner similar to those developed for the Folsom SPA - PPA. (See Section 2.2.2.2). All indoor unit demand factors are the same as those used for the Folsom SPA - PPA. The landscape unit demand factor for the commercial categories – Regional Commercial, Community Commercial, General Commercial, Office Park and Mixed-Use Non Residential – is 75 percent of ETo (compared to 85 percent of ETo for the Folsom SPA - PPA). The landscape unit demand for the Major Circulation category is also 75 percent of ETo. The reduction from 85 to 75 percent of ETo compared to the Folsom SPA - PPA will require the commercial categories to develop landscape plans that include more native and low-water using plantings as well as greater use of natural non-irrigated groundcover than in the Folsom SPA - PPA.[87] The landscape unit demand factor for the school and park categories remains at 85 percent of ETo because residents are most likely to demand grass covered areas in parks and in many of the non-playfield areas at schools.

The unit demand factors for each class per unit of land area for each land use category in the Folsom SPA - RHA are provided in **Table 6-5**.

6.2 FOLSOM SPA – RHA NON-POTABLE WATER DEMAND

If the City of Folsom were to require that the Folsom SPA – RHA demand categories corresponding to those eligible for non-potable service under the Recycled Water General Permit to use non-potable water, then the Folsom SPA - RHA land-use categories in **Table 6-6** would likely be eligible. The corresponding acreage and potential demand values are provided in **Table 6-6** as well.[88]

Table 6-6
Folsom SPA - RHA
Potential Non-Potable Water Demands

Land-Use Category	Landscape Acreage (AC)	Demand (AF/YR)
Parks	142	531
Streetscapes	15	49
C/I/O Landscape	141	463
Schools Landscape	47	176
Total	345	1,219

[87] See discussion in Section 2.1.3.3. A requirement to install low water using plants and weather-based irrigation controllers, as well as the use of dedicated landscape irrigation meters could reasonably achieve a reduction in water use from 85% to 75% of ETo. Monitoring use through a dedicated meter would provide a check on the efficacy of a landscape plan and the weather-based controller.
[88] See Section 2.3 for eligible non-potable water demand categories in the Recycled Water General Permit.

6.3 Projected Water Demands for Folsom SPA

Table 6-7 applies the land-use assumptions in **Table 5-2 and Table 5-3** to the unit demand values in **Tables 6-1, 6-4** and **6-5**. The total estimated water demand for the Folsom SPA RHA in a normal year is 5,395 AF, assuming a 10% non-revenue water factor.[89] In a dry-year, total Folsom SPA - RHA demand is projected to increase to 5,547 acre-feet. Similar to the Folsom SPA – PPA, the dry-year increase is a result of increasing the normal year outdoor demand for all residential and non-residential demand categories by 5% and then applying the non-revenue water factor of 10%. The portion of the Folsom SPA - RHA that is within the EID service area is projected to have a water demand of 228 AF in a normal year and 235 AF in a dry year, as shown in **Table 6-7**. Finally, **Table 6-7** also provides an indication of the balance between indoor and outdoor water demands for all land-use categories in both the Folsom and EID service areas.

[89] See footnote 43 for derivation of Non-Revenue Water factor.

Table 6-7
Folsom SPA - RHA
Normal and Dry-Year Demand Totals

Folsom Service Area				
Residential Land Use	Normal Indoor Total (AFY)	Normal Outdoor Total (AFY)	Normal Total (AFY)	Dry-Year Total (AFY)

EID Service Area Total	73	155	228	235
Total Demand	2,356	3,039	5,395	5,547

Assuming Folsom SPA - RHA residential and non-residential construction begins in 2013 and the 20-year required projection is applied, then the projected water demand shown in **Table 6-9** would be realized for the Folsom SPA-RHA.

Table 6-9
Folsom SPA – RHA
Projected Water Demands

Water Year	2033
Normal Year (AF/YR)	5395
Dry Year (AF/YR)	5547

SECTION 7 FOLSOM SPA – RHA WATER SUPPLY

The proposed water supply for the Folsom SPA – RHA is the same as the supply planned for the Folsom SPA – PPA that is analyzed in **Section 3**.[90] In summary, the City of Folsom plans to secure an assignment of a portion of NCMWC's Project Water supply. The existing agreement between SFP and NCMWC, and the existing non-binding memorandum of understanding between SFP and the City, provide the foundation for the City of Folsom to obtain an entitlement to the water supply through an assignment approved by the USBR. Consistent with the dry-year shortage provisions in the Renewal Contract, the supply ultimately assigned to the City of Folsom will be subject to a 25% reduction in "Critical Years." For purposes of the sufficiency analysis in **Section 8**, this reduction results in 6,000 AF being available in both single and multiple-dry year conditions. The normal year supply contractually available is projected to be 8,000 AF/YR, though the maximum diversion will be 6,000 AF/YR.

[90] The one difference that the Folsom SPA – RHA demand makes in the supply analysis is related to the demand pattern as explained in **Section 3.2.1.2**. Yet, because the dry-year demand estimate for the Folsom SPA – RHA is nearly the same (5,547 v. 5,577), 9.5 mgd is the projected maximum day demand estimate for the Folsom SPA – RHA.

SECTION 8 FOLSOM SPA – RHA WATER SUPPLY SUFFICIENCY ANALYSIS

Section 8 provides analysis of the sufficiency of the designated water supply for the projected demands for the Folsom SPA - RHA.[91] **Table 8-1** incorporates the demand projection in **Table 6-9**, including both normal and dry-year demand projections at 2033. It also contains the supply projections discussed in detail in **Section 3** and summarized in **Section 7**. Although 8,000 AF/YR is anticipated to be available through contract, for every normal water year between 2013 (start of demand) and 2033 (20-year projection), the City of Folsom will divert a maximum of 6,000 AF/YR to serve the Folsom SPA. For each single and multiple-dry year period, it is assumed that the 8,000 AF/YR base water supply is restricted pursuant to the "Shasta Critical" provisions discussed in **Section 3.2.1.1**, thereby reducing the base supply by 25% and resulting in a total supply of 6,000 AF.

Because construction of water infrastructure is expected to commence in 2011, and construction will continue for 2-3 years, water supplies will first need to be available some time in 2013. In a dry year in 2033, supplies are still estimated to exceed demand by about 450 AF/YR because annual dry-year demand will be approximately 5,547 AF/YR and supplies will be 6,000 AF/YR. Based upon the information in **Table 8-1** and the supporting analyses in **Sections 1, 5 and 6**, there will be a sufficient water supply for the Folsom SPA - RHA even in single and multiple dry year periods.

Table 8-1
Folsom SPA - RHA Supply/Demand Comparison

Year	Projected Baseline Water Demand (ac-ft/year)	Surface Water			Projected Surplus/ (Shortfall) (ac-ft/year)
		Hydrologic Year Type		Available Water Supply (ac-ft/year)	
2033	5,395	**Normal**		6,000	605
	5,547	**Single Dry**		6,000	453
		Multiple Dry	Year 1	6,000	453
			Year 2	6,000	453
			Year 3	6,000	453

[91] CWC § 10910 (c)(4) provides that "If the city or county is required to comply with this part pursuant to subdivision (b), the water supply assessment for the project shall include a discussion with regard to whether the total projected water supplies, determined to be available by the city or county for the project during normal, single dry, and multiple dry water years during a 20-year projection, will meet the projected water demand associated with the proposed project, in addition to existing and planned future uses, including agricultural and manufacturing uses."

CHAPTER 1 Introduction

This water infrastructure plan provides a discussion and summary of anticipated water infrastructure needs to serve the Folsom Sphere of Influence (SOI) area. The area is currently undeveloped and no public water supply or distribution system exists in the area. The City of Folsom intends to annex the area and provide water, wastewater, and recycled water services, in addition to other City services. Additional infrastructure plans are developed under separate reports for wastewater and recycled water infrastructure requirements in the SOI area. This water infrastructure plan is utilized to support the parallel environmental impact report document prepared by others and will serve as the basis for completing a detailed water infrastructure master plan.

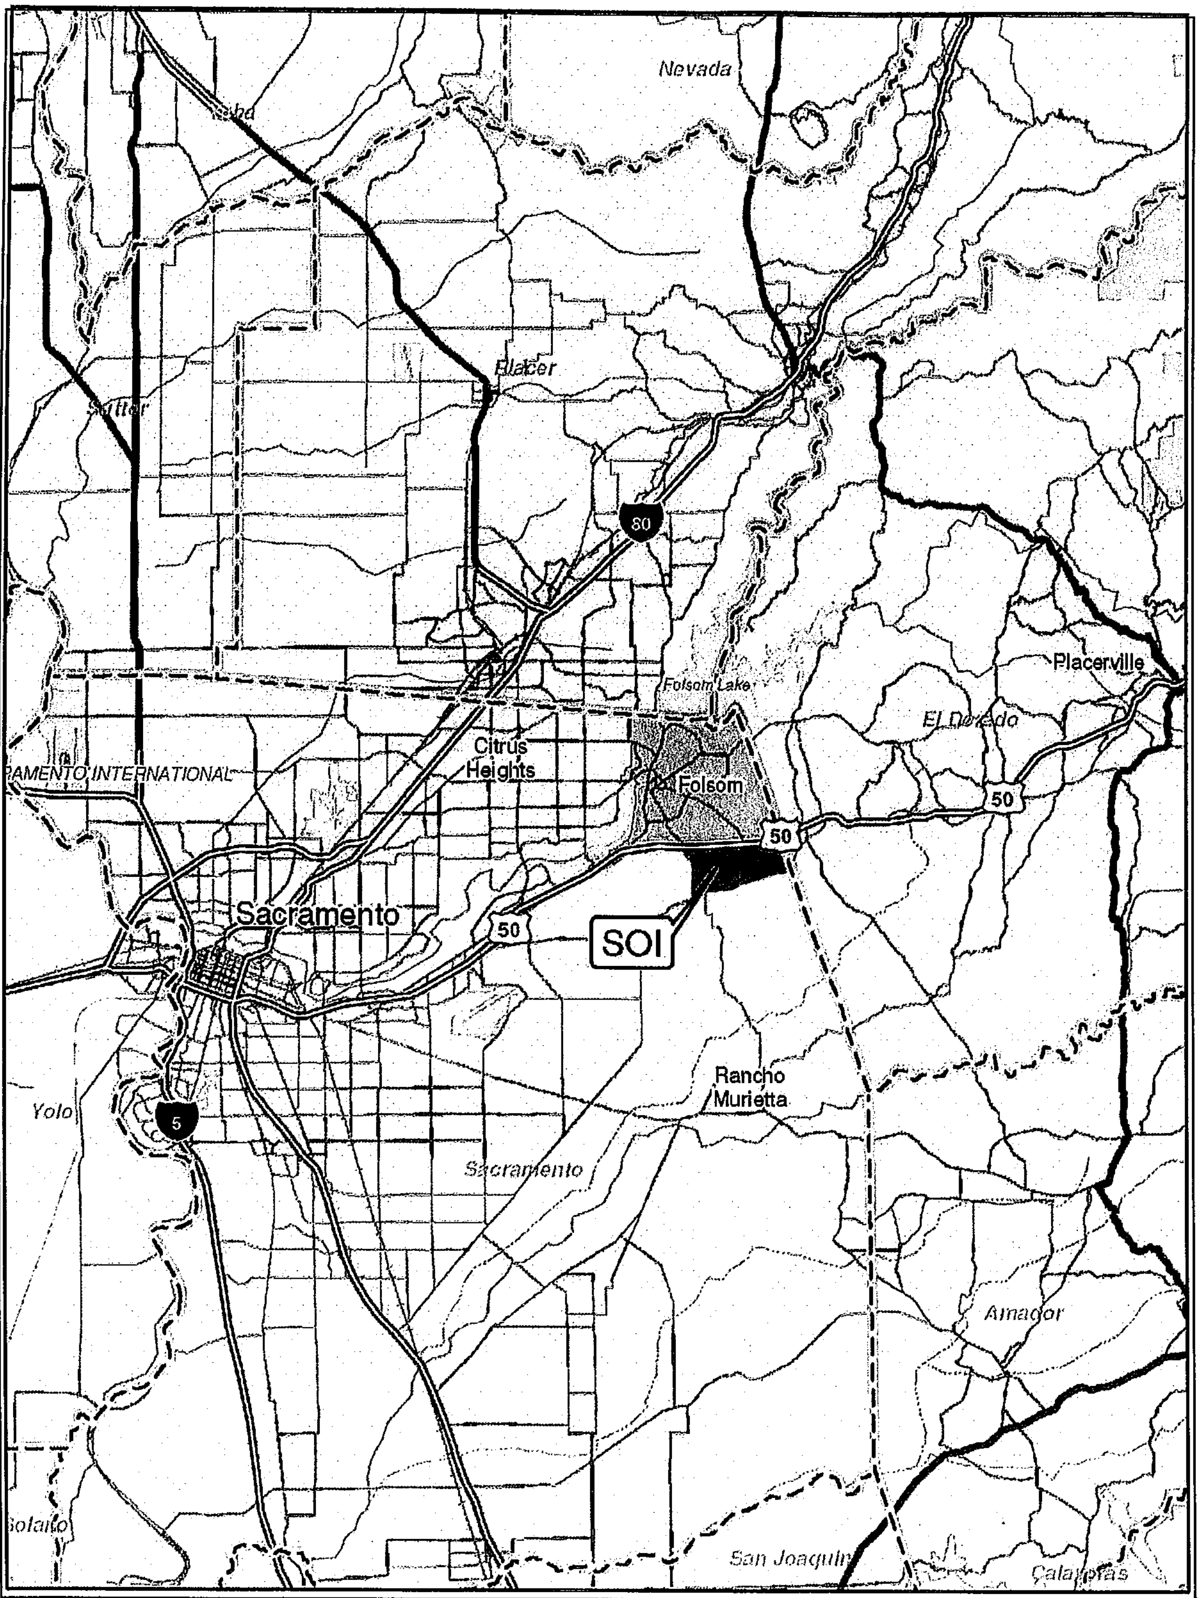
This draft report presents the analysis to date. There are many outstanding factors that will impact the water infrastructure requirements. As the development plans are refined, more detailed information is developed, and agency coordination continues, the infrastructure plan will be updated to reflect the changes.

1.1 SOI Background

The City of Folsom voters passed measure W in November 2004 to annex the SOI area. Adopted on July 27, 2004, the City has begun the process to annex the area through the Local Area Formation Commission (LAFCo), adopt a Specific Plan of the area, update the City's General Plan, and conduct an EIR/EIS process for the project. Currently seven property owners own all the land in the SOI area. The property owners have formed a group to coordinate and work with the City of Folsom and other entities to develop the project area.

1.2 Study Area Description

The SOI area consists of approximately 3,560 acres south of the existing Folsom southern boundary. The SOI area is bound by the El Dorado County Line on the east, White Rock Road on the south, Prairie City Road on the west, and Highway (HWY) 50/Folsom City limit on the north, as shown on Figure 1-1. The area is currently undeveloped and consists of rangeland and oak woodland areas. An aerial view of the project site is shown on Figure 1-2. Elevations range from 800 feet in the northeast corner, down to 300 feet in the southwest corner, and 240 feet in the northwest corner. Topography generally slopes down from east to west, although a main drainage feature runs from south to north in the eastern side of the area, discharging most of the study area drainage at the northwest corner of the project area. In addition, a ridge exists on the eastern side, such that the eastern most area is drained to the southeast corner of the project area. The eastern side consists of dry rangeland with a few stock ponds. The western side contains an oak woodland area and a few stock ponds.



City of Folsom Sphere of Influence Water Infrastructure Plan	**Figure 1-1** **Project Location**
J. CROWLEY GROUP SACRAMENTO, CA	***Figure provided by Mackay & Somps***

C:\Clients\City of Folsom\010-003 Folsom SOI\figure pdfs 092707

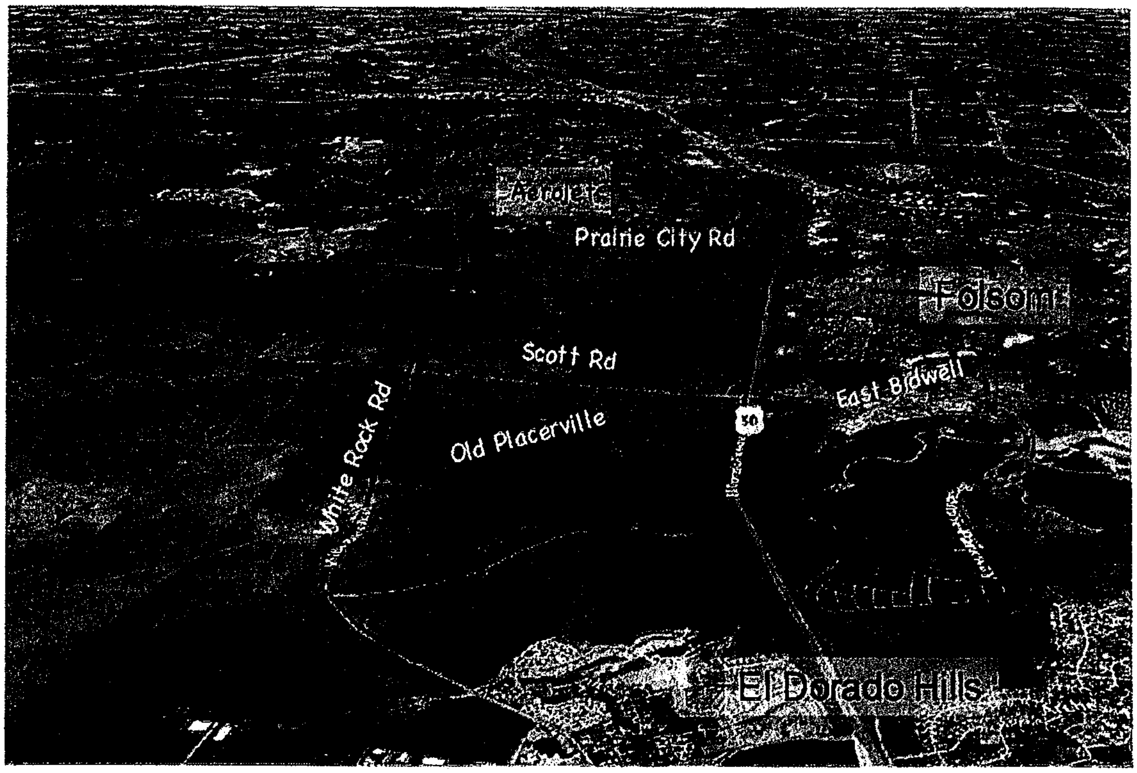


Figure 1-2. SOI Project Area

A small portion of the SOI is within the El Dorado Irrigation District (EID) service area boundary, as shown on Figure 1-1. Discussions with EID indicate they intend to maintain their service area boundary within Sacramento County. This analysis assumes that the SOI is not split into each respective service area, but remains as one system which will either be served entirely by Folsom or in part by EID. Folsom and EID will need to develop an agreement or memorandum of understanding regarding the customers whose water will be supplied and delivered by the other agency. The infrastructure needs with EID will not be completed within the time frame to submit this first version of the water plan. When the EID alternative is completed, either a revised water plan or a separate plan will be submitted.

CHAPTER 2 Land Use

Land use designations and proposed plans are provided in this chapter. The land use plan is provided by the landowners, and continues to be updated to address elements identified throughout the planning process. This document is based on the existing land use plan as of this date, but it is expected that some elements will change in the future and the resulting infrastructure requirements will require updating.

2.1 Land Use Designations

The proposed land use plan includes land uses for residential, commercial, office, public, and open space. Each land use is listed and defined below. The proposed land use categories are different than those presented in the Folsom 2005 Urban Water Management Plan (UWMP) (Tully and Young, 2006). Table 2-1 lists the proposed land use designations and the corresponding City of Folsom UWMP land use categories. This comparison is presented as the unit water demand factors from the 2005 UWMP are used to project water demands in this report.

Table 2-1. Land Use Category Comparison

SOI Land Owners Plan Land Use	Equivalent Folsom 2005 UWMP Land Use
SF – Single Family	Low Density Residential
SFHD – Single Family High Density	Medium Density Residential
MLD – Multi Family Low Density	Medium Density Residential
MMD – Multi Family Medium Density	Medium-High Density Residential
MHD – Multi Family High Density	High Density Residential
CCD – Central Commercial Mixed Use	High Density Residential
OP – Office Park	Moderate Intensity Office
CC – Community Commercial	Neighborhood Commercial/Office
GC – General Commercial	Regional Commercial/Office
PARK – Park	Park
LP – Local Park	Park
OS – Open Space	*none*
OSL – Landscaped Open Space	*none*
SCH –School	School
MAJ CIRC – Major Circulation	*none*
EXLC RW – Excluded Right of Way	*none*

SF (Single Family). Residential with dwelling unit (DU) densities of 2-3.9 DU/acre.

SFHD (Single Family High Density). Residential with densities of 4-6.9 DU/acre.

MLD (Multi Family Low Density). Multi family residential with densities of 7-11.9 DU/acre.

MMD (Multi Family Medium Density). Multi family residential with densities of 12-17.9 DU/acre.

MHD (Multi Family High Density). Multi family residential with densities of 18-25 DU/acre.

CCD (Central Commercial Mixed Use District). Residential mixed with commercial and retail usually on ground floor, located in central business district. Residential densities in range of 10-12 DU/acre.

OP (Office Park). Office parks.

CC (Community Commercial). Commercial land use with building usually only one story, located throughout area on arterial streets.

GC (General Commercial). Small commercial establishments, usually one story, located throughout development in smaller commercial areas such as intersections.

PARK (Parks). Regional and community parks, consisting of sports facilities, playgrounds, and/or turf areas.

LP (Parks – Neighborhood). A smaller park located in residential areas intended to serve immediately residential area.

OS (Open Space). Mostly void of structures and surface infrastructure, will contain greenway trails.

OSL (Landscaped Open Space). Open space land use category that is irrigated. Mostly median strips along arterial roadways.

SCH (School). High schools, junior high, elementary, and Country Day School sites with associated sports facilities and open space.

MAJ CIRC (Major Circulation). Arterial and other large secondary roadways with accompanying pavement, open space, and landscaped areas.

EXCL RW (Excluded Right of Way). Area within the SOI already owned by CalTrans as part of Highway 50.

2.2 Proposed Land Use

The proposed land use is shown on Figure 2-1 and summarized in Table 2-2. The largest land use by percentage is open space that is mostly located in the western side in the oak woodland area. Single family residential land uses are the next largest land use, followed by multi family land uses, and then the various commercial categories.

MAJ CIRC – Major Circulation	143	4%
EXCL RW – Excluded Right of Way	73	2%
Total	**3,559**	**100%**

2.3 Project Phasing

The current land owners are considering developing the project area in phases. However, actual phasing plans have not been developed at this time. It is likely that each landowner will determine their own phasing plans within their areas, as is common in other large-acreage developments with multiple land owners. The infrastructure requirements in this report are developed for the ultimate buildout conditions. As development in the first phase could be scattered throughout the project area, it is assumed that the basic infrastructure requirements will be required for the first phase. This analysis also examines the potential to integrate the SOI distribution system with the existing Folsom distribution system north of Highway 50 as well as the Aerojet Glenborough/Easton development to the west of the SOI.

CHAPTER 3 Potable Water Demand

This chapter presents the projected potable water demands for the proposed land use plan. The water demands estimated in this chapter include potential recycled water demand should recycled water not be available.

3.1 Unit Water Demands

Unit water demands are presented in the City of Folsom's 2005 UWMP. These unit water demands are used by Folsom for water planning efforts within the City's boundaries and the SOI area. The land use designations are matched to the UWMP designations in Chapter 2 of this report. Corresponding unit water demand designations are presented in Table 3-1. The UWMP listed demands as acre-feet per dwelling unit per year (AF/DU/yr) or acre-feet per acre per year (AF/acre/yr). Table 3-1 also converts the unit demand to a gallon per day per dwelling unit (gpd/DU) or per acre (gpd/acre) for comparison.

Table 3-1. Residential Unit Water Demands

Land Use	Indoor, AF/DU/yr	Outdoor, AF/DU/yr	Total, AF/DU/yr	Total, gpd/DU
SF	0.20	0.45	0.65	580
SFHD	0.20	0.36	0.56	500
MLD	0.20	0.36	0.56	500
MMD	0.20	0.20	0.40	357
MHD	0.20	0.10	0.30	268
CCD[a]	0.20	0.10	0.30	268

[a]CCD water demand estimate is split between non-residential and residential water use.

Table 3-2. Non-Residential Unit Water Demands

Land Use	Indoor, AF/acre/yr	Outdoor, AF/acre/yr	Total, AF/acre/yr	Total, gpd/acre
OP	2.0	4.0	6.0	5,357
CC	1.0	4.0	5.0	4,464
CCD[a]	1.0	4.0	5.0	4,464
GC	1.0	4.0	5.0	4,464
PARK	0.5	4.0	4.5	4,018
LP	0.5	4.0	4.5	4,018
OSL	0.0	4.0	4.0	3,571
SCH	3.0	4.0	7.0	6,250

[a]CCD water demand estimate is split between non-residential and residential water use.

3.2 Net Acre Factors

Unit water demands are applied to projected land use areas to identify total annual water demands. A net acre factor is used to reduce total acreage to actual acreage with water demands. This acreage reduction accounts for non-water demand areas, such as right of ways or pavement. The net acre factors also split water demands into indoor and outdoor water demands. The indoor/outdoor net acre factors are based on the indoor/outdoor unit water demands presented in the 2005 UWMP.

Table 3-3. Net Acre Factors

Land Use	Indoor	Outdoor	Total Net Acre Factor
OP	0.40	0.10	0.50
CC	0.40	0.05	0.45
CCD	0.40	0.05	0.45

3.3 Design Flow Peaking Factors

Design flow peaking factors are used to convert average annual demands to design flows used for sizing infrastructure. The City of Folsom recently updated their water master plan and hydraulic model. Design flow peaking factors are developed in Technical Memorandum No. 1 for the water master plan update (West Yost and Associates, February 10, 2006.) The design flow peaking factors selected are shown in Table 3-4. The maximum day peaking factor represents the maximum day to average day demand ratio and the peak hour peaking factor represents the peak hour to maximum day demand ratio.

Table 3-4. Design Flow Peaking Factors

Demand Condition	Peaking factor
Maximum day	1.9
Peak hour	1.8

3.4 Demand Projections

Water demand projections are summarized in Table 3-5. Potential recycled water demands are included in the total water demands should recycled water supply not be available. The demand projections in Table 3-5 are based on the maximum dwelling unit density of each of the residential land use categories. It is possible that the actual dwelling unit density of each of the residential land use categories may be less than the maximum. As a

result, the actual water demand may be less than the demand projected in Table 3-5. A comparison of the water demand and dwelling units projected in Table 3-5 based on maximum dwelling unit density with the water demand and dwelling units projected based on average dwelling unit density is provided in Table 3-6.

Table 3-6. Comparison of Projected Demand and Dwelling Units for Maximum and Average Dwelling Unit Density Assumptions

Dwelling Unit Density Assumption	Dwelling Units	Total SOI Demand, AF
Maximum	12,269	8,769
Average	9,924	7,331
Difference (maximum – average)	2,345	1,438

3.5 Potable Water Supply

The City of Folsom will obtain a new water source to serve the SOI area. Infrastructure requirements to deliver the supply to the SOI are currently under investigation. The projected annual demands for the land use plan area are approximately 8,769 acre-feet per year, including potential recycled water demands. As discussed in the previous section the projected annual demand in this report is based on the maximum dwelling unit density. Demands may be less if actual dwelling unit densities are less than the maximum. Demands may also be less if conservation efforts are implemented in the new development.

CHAPTER 4 Existing Water System and Other Adjacent Areas

This chapter describes the existing City of Folsom distribution system to provide a better understanding of the issues to consider when connecting the SOI system with the existing system. The pressure zones and operations are briefly discussed. A summary of the distribution system needs and planned improvements is provided. In addition, the Glenborough/Easton distribution system is discussed.

4.1 Existing Folsom Distribution System

The City of Folsom's distribution system is divided into two distinct systems. The system north of the American River is supplied by the San Juan Water District, and is not included further in this analysis. The larger water distribution system serves the largest area of the City that is located south of the American River and north of Highway 50. Water is treated at the City's water treatment plant on the north side of town. Treated water is pumped or flows by gravity into the pressure zones. There are six main pressure zones in the system, with some sub-zones. The zone elevation boundaries are summarized in Table 4-1. The SOI pressure zones are designed to mirror the service zone elevations of the existing system for ease of operations when integrating the SOI system with the existing system.

Table 4-1. Service Zone Elevations

Zone	Service Elevation Range, feet
Nimbus	Up to 180
1	Up to 280
2	280-380
3	341-466
4	466-616
5	591-716
6	716-790

Note: Reproduced from Draft TM No. 4 Water System Master Plan Update – Distribution System Analysis, West Yost & Associates, April 5, 2007.

Zone 1 serves the lower west side of Folsom. The system is mostly gravity fed from the finished water reservoirs at the treatment plant. In addition, there are five main pressure-reducing interconnections with Zone 2. The South Reservoir is filled by gravity from the Zone 1 system and provides pressure and storage needs for the zone. Zone 1 abuts the Highway 50 corridor in the southwest corner of the City.

Zone 2 is the largest of Folsom's service zones in terms of area and demand served. The Zone 2 Booster Pump Station (BPS) is located at the treatment plant site and pumps from the finished water reservoirs into the distribution system. The Tower Reservoir and the two East Reservoirs provide storage and pressure control. Zone 2 can also be fed through pressure-reducing stations from Zone 3. Zone 2 abuts the Highway 50 corridor along Iron Point Road from approximately Prairie City Road to Broadstone Parkway.

Zone 3 is a unique shape due to topography. Zone 3 covers the northeast section of Folsom to the east boundary, then wraps around in a narrow band, across East Bidwell Street to the Highway 50 corridor. The Zone 3 pumps, located at the water treatment plant, feed the system. Cimmaron Hills Reservoir provides storage and pressure control for the Zone 3 area in the northeast. Zone 3 is also fed by the East Area BPS. The East Area pumps also draw from the finished water reservoirs. The two Foothills Reservoirs provide storage and pressure control for the Zone 3 area in the southeast portion of the city.

The Zone 4 BPS is located on the east side of the City and draws from the East Area BPS fed system in Zone 3. The Broadstone Reservoir provides storage and pressure control.

The Zone 5 BPS pumps from the Zone 4 system, with Carpenter Hill Reservoir providing storage and pressure control.

The Zone 6 BPS in the southeast corner of the City draws from Zone 5, and is a hydropneumatic system due to the small service area of the zone.

4.2 Existing Distribution System Needs and Planned Improvements

The Water System Master Plan 2005 Update (West Yost and Associates, TM 1, 2, 3, and 4) evaluated future system improvements based on General Plan buildout conditions in 2009, when it is expected that residential land use will be substantially built out. Recommended improvements are discussed in Technical Memorandum No. 4 (West Yost and Associates, April 5, 2007). The recommendations call for an additional 10 million gallons (MG) of storage to meet emergency storage capacity goals, with at least 7 million gallons located at the treatment plant site, and at least 1.2 million gallons in Zone 2. Low pressure and low fire flow areas are identified with various recommendations to improve conditions through pipe replacement, relocating zone boundaries, or other localized actions.

System-wide zone issues are also addressed. Pressure-reducing valve stations are recommended to supply Zone 1 from Zone 2 during high demand periods. Zone 2 experiences storage issues due to the distance and head loss in the system that prevent utilization of stored water in the Tower Reservoir, and inhibit the ability to fill the East Reservoirs. A parallel main is recommended to reduce pumping heads and improve hydraulics, allowing the Tower Reservoir and East Reservoirs to operate as planned.

Recommendations for Zone 3 include isolating the Zone 3 Cimmaron system with pressure reducing valves (PRVs), which is expected to allow the rest of Zone 3 to operate correctly. Zones 4 through 6 do not have any high priority recommendations. However, results indicate the systems will be operated at the upper limit of flow and storage capabilities, and actual performance should be monitored and needs re-evaluated over time. Other second priority recommendations and infrastructure replacements projects consistent with normal asset management that are provided in the Water System Master Plan 2005 Update are not mentioned here.

4.3 Glenborough/Easton Distribution System

The Glenborough/Easton development will be served water supply by the City of Folsom. A parallel planning effort is underway to investigate supply connections to the existing Folsom distribution system. The development would logically connect to the City's Zone 1 and Zone 2 areas. However, the existing system may be capacity limited and not able to provide the entire development with its supply needs. The parallel analysis is investigating multiple connection points, with consideration of using the proposed SOI water treatment plant and pressures zones as a second supply source.

4.4 System Wide Planning Considerations

A summary of the existing system and infrastructure needs is discussed in this report to provide a better understanding of the issues and operations involved in integrating the SOI system with the existing system. The analysis also considers the needs of the future development, Glenborough/Easton, which will be served by the existing system for the first phases. System wide planning considerations may involve providing additional storage, treatment, and/or pumping capacity in the SOI or Glenborough/Easton developments for the purposes of improving operations for the system as a whole. Elements that support system-wide improvements will be identified and discussed.

CHAPTER 5 SOI Distribution System Analysis

This chapter develops infrastructure layout options for the water distribution system within the SOI area. The SOI distribution system is developed with consideration to demand locations, main pipe alignments, storage needs and locations, pressure zones, and pumping requirements. Integration of the new SOI system with the existing distribution system are discussed in Chapter 6 of this report.

A hydraulic model of the SOI system was developed in this analysis using MWSoft's Infowater software, the GIS-based version of H2ONet. The development of a computer hydraulic model makes it possible to analyze the expected system performance at varying demand conditions such as maximum day and peak hour. The EID service area within the SOI, SOI pressure zones, demand assignment, model assumptions, and system infrastructure design options and analysis are described in this chapter.

5.1 EID Service Area within the SOI

Approximately 150 acres on the northeast east end of the SOI area, adjacent to the Sacramento/El Dorado county line is part of the El Dorado Irrigation District service area. Folsom and EID are in the process of discussing this issue and evaluating potential service options. No service area splits have been performed for this analysis.

The EID service area is located within two of the pressure zones. Approximately one quarter of the Zone SOI 5 ground area and two-thirds of the Zone SOI 6 ground area is located within the EID service area. Approximately 430 acre-feet of demand is attributable to the EID service area. A recent EID supply analysis, "2007 Water Resources and Service Reliability Report, June 25, 2007", indicates the El Dorado Hills system contains 746 acre-feet per year of excess supply, which is equivalent to 933 new connections. The El Dorado Hills system serves all of the EID's eastern service area. Table 5-1 provides a comparison of the EID service area demand within the SOI.

Table 5-1. Comparison of EID Water Demands

Area	Average Annual Demand, AF	Dwelling units[a]	Notes
SOI EID service area	427	536	Water demand and dwelling units based on maximum dwelling unit density.
SOI total Zones SOI 5 and SOI 6	1,313	1,597	Water demand and dwelling units based on maximum dwelling unit density.

[a]Dwelling units estimated within the SOI are based on maximum dwelling unit density by residential land use category.

If EID were to serve their SOI area, a booster pump station would be required to boost water from the existing pressure zone at the El Dorado County line adjacent to the SOI. The adjacent EID service area is at a lower hydraulic grade line than what is required to serve Zones SOI 5 and SOI 6. It is assumed that only one agency will provide water service to this area; this prevents parallel construction of potable water facilities and pipelines immediately adjacent to one another. The proposed water system for the Folsom-only system is described in this chapter. The proposed system for the combined Folsom/EID service scenario is still under development with EID and will be amended to this report or submitted separately once coordination completed.

5.2 SOI Pressure Zones – General Description

The SOI pressure zones are designed to mirror the service zone elevations of the existing system for ease of operations when integrating the SOI system with the existing system. This section provides a general description of the pressure zones in the SOI as they exist in all infrastructure layout options. The infrastructure layout options are discussed later in this chapter.

Zone SOI 2 is the lowest elevated pressure zone in the SOI, and is located in western most area of the development from Prairie City Road to just west of Scott Road. It serves approximately half the total demand of the SOI. The Zone SOI 2 demand is served directly from the water treatment plant along Prairie City Road. A ground storage facility for Zone SOI 2 is located adjacent to the SOI water treatment plant. In option 1b (discussed later in this chapter), an additional Zone SOI 2 reservoir is added on the east side of Zone SOI 2. There is potential to connect Zone SOI 2 to the existing system Zone 2 by constructing a pipeline along the Prairie City Road crossing of HWY 50.

Zone SOI 3 is located in the central portion of the development from just west of Scott Road to just west of Placerville Road, and serves approximately one-fourth of the total demand of the SOI. A gravity storage facility for Zone SOI 3 is located just west of Placerville Road north of White Rock Road. There is potential to connect Zone SOI 3 to the existing system Zone 3 by constructing a pipeline along Placerville Road under HWY 50.

Zone SOI 4 is located along the Placerville Road corridor, and services approximately ten percent of the total demand of the SOI. A gravity storage facility for Zone SOI 4 is located just east of Empire Ranch Road. As discussed later in this chapter, the infrastructure is designed to maintain a system pressure between 40 and 80 pounds per square inch (psi) during maximum day demand conditions. The Zone SOI 4 is designed to mirror the existing system pressure Zone 4 ground elevations. The existing system Zone 4 ground elevation range is 466 ft to 616 ft, which is a large elevation range for a pressure zone (150ft). Because the ground elevations in Zone SOI 4 are at the bottom of the Zone 4 elevation range, the Zone SOI 4 maximum day demand pressure results in values around 100 psi in all infrastructure scenarios. This is higher than the City's typical design standards. In this analysis, it was the intent to maintain the same zone elevation range as the existing system Zone 4 for ease of existing system and SOI system integration.

Zone SOI 5 is located in the southeast area of the development, just east of Placerville Road to the Sacramento/El Dorado county line, and serves approximately 15 percent of the total demand of the SOI. A gravity storage facility for Zone SOI 5 is located just east of Empire Ranch Road, near Hwy 50. The Zone SOI 5 storage facility is also sized to serve Zone 6 peak hour demands. Approximately two thirds of the Zone SOI 5 ground area is located within the EID service area. It is assumed that only one agency will provide water service to this area; this prevents construction of two sets of potable water facilities and pipelines immediately adjacent to one another. The proposed water system for the Folsom-only system is described in this chapter. The proposed system for the combined Folsom/EID service scenario will be amended to this report or submitted separately once coordination with EID is complete. In addition, there is potential to connect Zone SOI 5 to the existing system Zone 5 by constructing a pipeline along the future Empire Ranch Road crossing of HWY 50.

Zone SOI 6, the highest elevated pressure zone, is located in the northeast corner of the development between Empire Ranch Road and the Sacramento/El Dorado county line. The Zone SOI 6 is the smallest pressure zone and serves approximately one percent of the total SOI demand. All demands in Zone SOI 6 are served through a booster facility from Zone SOI5. An additional booster pump sized for fire flow demands (3,000 gpm) is required because there is no storage tank within Zone SOI 6. The Zone SOI 6 equalization, emergency, and fire flow supply is included in the Zone SOI 5 storage tank volume. Approximately two-thirds the ground area of Zone SOI 6 is located within the EID service boundary. Similar to Zone SOI 5, it is assumed that only one agency will provide water service to this area; this prevents construction of two sets of potable water facilities and pipelines immediately adjacent to one another. The proposed water system for the Folsom-only system is described in this chapter. The proposed system for the combined Folsom/EID service scenario will be amended to this report or submitted separately once coordination with EID is complete.

5.3 Demand Assignment

The demands estimated by land use parcel in Chapter 3 are grouped into demand allocation areas and assigned to the nearest nodes. The demand by pressure zone and by land use is shown in Table 5-2. Appendix B contains a system map showing the maximum day demand per node.

5.4 Model Assumptions

A distribution system consisting of storage, booster pumping stations, and transmission main pipelines was developed and input into the model. Sizing and modeling assumptions are based on factors presented in the Water System Master Plan 2005 Update Technical Memorandums No. 2 and 4 (West Yost and Associates, May 30, 2006, April 5, 2007), and are summarized in Table 5-3. A figure illustrating the ground elevation assumption at each SOI system node is presented in Appendix B.

Table 5-3. Infrastructure Sizing and Modeling Assumptions[a]

Element	Value
Storage requirement	Operational Storage at 25% maximum day demand plus Emergency storage at 75% maximum day demand plus Fire Flow based on largest fire flow requirements in zone
Pressure range	40 psi – 80 psi during normal max. day operations Minimum 30 psi during peak hour operations Minimum 20 psi in vicinity of fire
Pipeline velocity	7-8 feet per second maximum for daily operation up to 10 feet per second for fire flow operation
Pipeline roughness coefficient	130 for new pipes
Fire flows	
Single-Family	1,500 gpm for 2 hours, 0.18 million gallons storage
Multi-Family	2,500 gpm for 2 hours, 0.30 million gallons storage
Commercial/Industrial	3,000 gpm for 3 hours, 0.54 million gallons storage
Schools	4,000 gpm for 4 hours, 0.96 million gallons storage

[a]Values from Water System Master Plan 2005 Update Technical Memorandum No. 2, Draft Water System Computer Model Update May 30, 2006 and No. 4, Draft Distribution System Analysis.

5.5 SOI System Development

Four infrastructure layout options are developed. These infrastructure options assume that all demand within the SOI, including those within the EID service area, is served from the SOI water treatment plan. A second scenario investigates EID serving their service area on the east side of the SOI, and will either be amended to this document, or submitted separately, once the analysis and coordination with EID is completed.

Each of the SOI infrastructure layout options include major transmission mains, storage, and booster pumping requirements. The infrastructure layout options are listed as follows and described below:

Option 1a.	All supply through Zone SOI 2
Option 1b.	All supply through Zone SOI 2, Zone SOI 2 gravity storage
Option 2.	Transmission main to Zone SOI 3
Option 3.	Zone SOI 3 supply through Zone SOI 2, Transmission main to Zone SOI 4

<u>Option 1a. All supply through Zone SOI 2</u>

In this option, all SOI demand is supplied through in line boosting from one zone to the next highest zone. This option was developed to minimize the necessary transmission main pipeline by delivering water from the water treatment facility through each zone in series formation from the lowest zone (Zone 2) uphill to the highest zone (Zone 6). The Zone SOI 2 ground storage was located at the water treatment facility because this location is near the existing system and Glenborough/Easton. Additional storage volume could be added to the Zone SOI 2 ground tank to provide additional equalization, emergency, and fire flow supply and hydraulic head for the existing system Zone 2, and for the Glenborough/Easton system, adjacent to the SOI to the west. The Option 1a infrastructure layout is provided on Figure 5-1, and the hydraulic schematic is provided on Figure 5-2. Figures illustrating maximum day demand and peak hour demand pressure contours are provided in Appendix C.

Option 1b. All supply through Zone SOI 2, Zone SOI 2 gravity storage
This option is similar to Option 1a, all SOI demand is supplied through in line booster pumping to the next highest zone, with the addition of a Zone SOI 2 gravity storage tank located east of Placerville Road. In this option, the Zone SOI 2 ground tank adjacent to the water treatment facility is half the size of the other options (4.5 MG) and the gravity storage tank is 4.5 MG. This Zone SOI 2 storage variation was analyzed to examine the benefits of multiple storage locations within this large zone to provide adequate fire flow supplies and to allow for adequate system pressures during peak demand periods and fires. Ground storage at the water treatment facility, which is located close to the existing system Zone 2, could help issues in the existing system such as lack of Zone 2 storage and low pressure issues on the south side of the existing system. Further analysis of the benefits of one or multiple storage facilities in Zone SOI 2 is required when the system design has progressed to contain a more complete piping system. The Option 1b infrastructure layout is provided on Figure 5-3, and the hydraulic schematic is provided on Figure 5-4. Figures illustrating maximum day demand and peak hour demand pressure contours are provided in Appendix C.

Option 2. Transmission main to Zone SOI 3
Zone SOI 3 is fed through a dedicated transmission main from the SOI water treatment facility. Zones SOI 4, SOI 5, and SOI 6 are fed through in-line boosters from Zone SOI 3. Zone SOI 2 is not hydraulically connected to any other SOI zone and is fed directly from the SOI water treatment facility. Because Zone 2 feeds approximately half the SOI system demand, the intent of this infrastructure option was to eliminate additional dependency on Zone SOI 2 from the other zones as in Option 1a and 1b. This option increases system reliability from Option 1a and 1b because flow to Zones SOI 3, SOI 4, SOI5, and SOI 6 do not rely on Zone SOI 2 infrastructure or operations and is delivered to Zone SOI 3 directly from the water treatment facility. Additional transmission pipeline is required for this option due to the required approximately 15,000 feet of pipe of dedicated transmission main from the water treatment facility to Zone SOI 3. The Option 2 infrastructure layout is provided on Figure 5-5, and the hydraulic schematic is provided on Figure 5-6. Figures illustrating maximum day demand and peak hour demand pressure contours are provided in Appendix C.

Option 3. Zone SOI 3 supply through Zone SOI 2, Transmission main to Zone SOI 4
Zone SOI 3 is supplied through in-line boosters from Zone SOI 2. A dedicated transition main from the SOI water treatment plant delivers Zone SOI 4, Zone SOI 5, and Zone SOI 6 water to the Zone SOI 4 gravity storage facility just west of Empire Ranch Road. Zones SOI 5 and SOI 6 demand is boosted out of the Zone SOI 4 storage facility. The Zone SOI

4 demand is served from the Zone 4 gravity storage tank. Zones SOI 2 and SOI 3 are not hydraulically connected to Zones SOI 4, SOI 5, and SOI 6. Similar to Option 2, this option improves system reliability compared to Options 1a and 1b because the demand on the east side of the system is not delivered through Zones SOI 2 and SOI 3 on the west side of the system, but is delivered directly from the water treatment facility. This option requires the largest amount of transmission pipeline of all the infrastructure options due to the dedicated transmission pipeline from the water treatment plant to the Zone SOI 4 gravity storage tank. The Option 3 infrastructure layout is provided on Figure 5-7, and the hydraulic schematic is provided on Figure 5-8. Figures illustrating maximum day demand and peak hour demand pressure contours are provided in Appendix C.

Table 5-4 provides a comparison of the backbone pipeline required by infrastructure option.

Table 5-4. SOI Pipeline Requirements by Option

Pipe diameter	Option 1a	Option 1b	Option 2	Option 3
12	90,443 ft	90,443 ft	104,632 ft	90,150 ft
16	17,882 ft	17,699 ft	17,584 ft	14,523 ft
18	3,677 ft	3,677 ft	3,677 ft	3,677 ft
20	4,847 ft	4,847 ft	4,734 ft	27,527 ft
24	7,469 ft	11,798 ft	22,585 ft	6,679 ft
30	15,874 ft	15,874 ft	0 ft	15,874 ft
Total	**140,192 ft**	**144,338 ft**	**153,212 ft**	**158,430 ft**

5.6 SOI Storage Reservoirs

Table 5-5 provides the volume and base elevations of each reservoir including the pressure zone it serves. The storage tanks maintain and stabilize pressure as well as provide additional water supply during peak hour demand periods (equalization), emergencies, and fire flows. The storage reservoirs are sized based on the City's storage sizing requirements listed in Table 5-3. The SOI 5 gravity tank is sized to also provide equalization, emergency, and fire flow storage for Zone SOI 6. All reservoirs in the system are modeled as tanks.

Table 5-5. SOI Storage Reservoirs

Storage Reservoir	Pressure Zone Served	Option 1a		Option 1b		Option 2		Option 3	
		Volume, MG	Base Elevation, ft	Volume, MG	Base Elevation, ft	Volume, MG	Base Elevation, ft	Volume, MG	Base Elevation, ft
SOI 2 ground	SOI 2	9.0	320	4.5	320	9.0	320	9.0	320
SOI 2 gravity	SOI 2	--	--	4.5	472	--	--	--	--
SOI 3 gravity	SOI 3	4.5	558	4.5	558	4.5	558	4.5	558
SOI 4 gravity	SOI 4	2.5	708	2.5	708	2.5	708	3.0	708
SOI 5 gravity	SOI 5 and SOI 6	4.0	808	4.0	808	4.0	808	4.0	808

5.7 SOI Booster Pump Stations

The pressure zone served, capacity, and horsepower for each BPS are shown in Table 5-6. The booster pump stations are sized to provide maximum day demand for the zone being served as well as any additional zone drawing supply through the BPS. The zones being served by each BPS are noted for each option in Table 5-6. The Zone SOI 6 booster pump station is sized to provide maximum day and peak hour demand because there is no storage facility is Zone SOI 6. An additional booster pump is required to provide fire flow supply to Zone 6.

The horsepower (hp) required for each BPS is calculated based on the following equation:

$$\text{Required horsepower} = Q * TDH / (\text{eff}) * (3{,}960)$$

Where Q = required flow, gpm
TDH = total dynamic head, ft
eff = pump efficiency, assumed to be 0.75

Table 5-6. SOI Booster Pump Stations Capacities by Zone

Booster Pump Station	Option 1a		Option 1b		Option 2		Option 3	
	Capacity, gpm	Power, hP	Capacity, gpm	Power, hP	Capacity, gpm	Power, hP	Capacity, gpm	Power, hP
SOI 2	10,200 gpm (serves all zones)	600 hp	10,200 gpm (serves all zones)	600 hp	5,200 gpm (serves SOI 2 only)	300 hp	7,600 gpm (serves SOI 2 and SOI 3)	400 hp
SOI 3	5,000 gpm (serves SOI 3, SOI 4, SOI 5, SOI 6)	400 hp	5,000 gpm (serves SOI 3, SOI 4, SOI 5, SOI 6)	400 hp	5,000 gpm (serves SOI 3, SOI 4, SOI 5, SOI 6)	450 hp	2,500 gpm (serves SOI 3 only)	400 hp
SOI 4	1,070 gpm (serves SOI 4 only)	100 hp	1,070 gpm (serves SOI 4 only)	100 hp	1,070 gpm (serves SOI 4 only)	100 hp	2,700 gpm (serves SOI 4, SOI 5, SOI 6)	450 hp
SOI 5	1,571 gpm (serves SOI 5 and SOI 6)	150 hp	1,571 gpm (serves SOI 5 and SOI 6)	150 hp	1,571 gpm (serves SOI 5 and SOI 6)	150 hp	1,571 gpm (serves SOI 5 and SOI 6)	150 hp
SOI 6[a]	20 gpm (serves SOI 6 only)	10 hp	20 gpm (serves SOI 6 only)	10 hp	20 gpm (serves SOI 6 only)	10 hp	20 gpm (serves SOI 6 only)	10 hp

[a]An additional fire flow booster pump of 3,000 gpm is required to supply fire flow to zone SOI 6.

5.8 SOI Water Treatment Facility

The SOI water treatment facility is to be located within the SOI area on the east side of Prairie City Road. The capacity of the treatment facility is based on the supply capacity of the Sacramento River supply source. It is estimated the treatment facility will require 20 acres based on conventional treatment including flocculation, sedimentation, and filtration, plus extra space required for on site raw water storage. The on site raw water storage element will significantly impact site area requirements. The City of Folsom may decide to increase raw water storage capabilities for system-wide reliability purposes. Total raw water storage requirements should be discussed and finalized soon so that the proper plant site area can be evaluated and identified.

CHAPTER 6 Integration of SOI and Existing System

This chapter describes the effort to-date regarding the integration of the SOI water system with the City's existing system. Also described are next steps required to complete the integration analysis.

6.1 Initial Analysis of Integration of SOI and Existing System

The City of Folsom's existing system H2ONet hydraulic model updated by West Yost and Associates in October 2006 was used to analyze the integration of the SOI system with the existing water system. The October 2006 model contains 2005 system demands. The City's existing system model was opened in MWSoft's Infowater, the GIS based version of H2ONet in order to integrate the existing model with the SOI system model. The SOI system was connected to the existing system at Zones 2, 3, and 5. Connecting the existing system to the SOI at these zones is the most practical due to HWY 50 crossing options and existing connecting pipe availability.

When the SOI system model was connected to the existing system 2005 demands model, the existing system typically pulled approximately 2,000 gpm from the SOI system; most of the flow passing from Zone SOI 2 to the existing Zone 2. The pressure in the south portion of the existing system Zone 2 near the SOI generally increased by 5 psi. It should be noted that based on an August 3, 2007 letter from West Yost and Associates to the City of Folsom, there may be inaccuracies in the existing system model due to the use of GIS shape files that did not incorporate several significant pipe upgrades that have been installed. The use of an updated existing system hydraulic model would enable this analysis to more accurately reflect SOI system impacts on the existing system.

Although the impacts of the future Glenborough/Easton system Phase 1 demands (2,000 gpm) have been analyzed against the existing system hydraulic model (2005 demands), the impacts of connecting the Glenborough/Easton system to the existing system at the same time as the SOI system is connected has not been analyzed. This model analysis has not been completed because this requires the use of the City of Folsom existing system hydraulic model with buildout demands as well as increased supply capacity and current infrastructure improvements. Buildout demands in the existing model are required because this reflects the demands that would be occurring in the existing system at the time of completion of the SOI and Glenborough/Easton developments. An analysis of an integrated system coordinating Glenborough/Easton, the existing system, and the SOI system would not be accurate if based on connecting to an existing system with 2005 demands and capacity. This analysis can be completed once the updated/buildout demands hydraulic model is completed.

6.2 Analysis Next Steps

In order to complete the analysis on the integration of the SOI and the City's existing system, the following next steps should be taken:

1. Update the existing system hydraulic model to reflect current infrastructure improvements that exist within the system.
2. Complete the City's hydraulic model for the existing system at buildout water demands and buildout supply and infrastructure capacity.
3. Integrate the Glenborough/Easton system demands to the existing system/SOI system integration analysis. Analyze the impacts on the existing system as a result of connecting to the Glenborough/Easton and SOI systems at buildout demand conditions. Examine the resulting pressure changes and significant hydraulic grade line impacts on the existing system.

CHAPTER 7 SOI Distribution System Cost Estimate

The estimated construction cost of the infrastructure options are developed at a conceptual level in this chapter.

7.1 Unit Costs

Table 7-1 provides a summary of the unit cost assumptions for this conceptual cost estimate. Also provided are the references and/or assumptions used to estimate the unit costs. The cost estimates are based on using construction unit costs of similar facilities when possible. When such costs are not available, construction cots are estimated from available cost curves or other assumptions.

Table 7-1. Unit Cost Assumptions

Infrastructure Component	Unit Cost	Reference/assumption
Pipeline	$18/in-dia/linear foot	Based on recent bid tabs and completed construction for projects for local water agencies, including Freeport Regional Water Authority.
Booster pump station	$250/gpm	Treated water. Based on construction costs of service water pumping stations cost curve (Robert L. Sanks, Pumping Station Design, 1989, Figure 29-6) and based on recent project costs for Sacramento area booster station projected to January 2007.
Treated water storage tank	$0.50/gallon	Based on discussions with local contractors and water agencies on recent reservoir construction with foundation and appurtenances.
Water treatment facility	$2.5/gallon	Based on letter regarding the Freeport/Folsom cost estimate provided by Brown and Caldwell on September 19, 2007.

7.2 Construction Cost Contingency

Because of limitations of costs estimates based on preliminary design, allowances must be made for variations in final length and depth of pipelines and other structures, adverse construction conditions, and other unforeseeable difficulties that may increase the final construction cost. A contingency allowance of 30 percent of the estimated construction contract cost is applied for this analysis.

7.3 Conceptual Construction Cost

The infrastructure requirements and conceptual level costs for Option 1a, 1b, 2, and 3 are provided in Table 7-2. These conceptual level cost estimates are considered to be a planning level estimate for the purposes of comparing infrastructure options. The cost of operations and maintenance for each alternative is not included in this analysis. In addition, this conceptual cost estimate does not include project costs such as engineering, construction management, and administration costs. Detailed conceptual construction cost tables by option are provided in Tables 7-3 through 7-6.

Table 7-2. Summary of Conceptual Cost Estimates

Cost Item	Cost, $ million			
	Option 1a	Option 1b	Option 2	Option 3
Water treatment plant[a]	$38	$38	$38	$38
Pipeline				
12-inch	$20	$20	$23	$19
16-inch	$5	$5	$5	$4
18-inch	$1	$1	$1	$1
20-inch	$2	$2	$2	$10
24-inch	$3	$5	$10	$3
30-inch	$9	$9	$0	$9
Pipeline subtotal	$39	$41	$40	$46
Booster pump station	$6	$5	$4	$5
Storage	$10	$11	$10	$9
Construction cost	$93	$95	$93	$97
Construction contingency (30%)	$28	$28	$28	$29
Total	**$121**	**$123**	**$120**	**$126**

[a]Costs include WTP costs based on required capacity for SOI, 15 mgd.

CHAPTER 8 EID Service Alternatives

EID maintains a service area within the SOI area of approximately 150 acres. Infrastructure alternatives for EID to provide service to the east side of the SOI are under development in coordination with EID. Once completed, the alternatives will be inserted into this report.

CHAPTER 9 Next Steps

This draft report presents the analysis findings as of this date. Coordination continues with the other SOI-related projects and with neighboring agencies. The following lists items to address next as the environmental review process moves forward.

1. Continue coordination with EID to develop service scenarios for the east side of the SOI. Update analysis or prepare a separate plan once alternative is selected and agreed upon.
2. Continue coordination with EID on a parallel track to develop required policy and agreements to support the selected service scenario.
3. Coordinate review of draft report with environmental report efforts and modify analysis as necessary.
4. Continue coordination with landowners group to develop and refine infrastructure options as phasing and parcel information is updated.
5. Update SOI system demand estimates and required infrastructure based on a more detailed parcel analysis resulting in buildable dwelling unit densities.
6. Consider unit water demands, impacts on total water demand and infrastructure requirements, and potential policies that would reduce total demands.
7. Update the existing system hydraulic model to reflect current infrastructure improvements that exist within the system.
8. Complete the City's hydraulic model for the existing system at buildout water demands and buildout supply and infrastructure capacity.
9. Integrate the Glenborough/Easton system demands to the existing system/SOI system integration analysis. Analyze the impacts on the existing system as a result of connecting to the Glenborough/Easton and SOI systems at buildout demand conditions. Examine the resulting pressure changes and significant hydraulic grade line impacts on the existing system
10. Provide further analysis of the benefits of one or multiple storage facilities in Zone SOI 2 when the system design has progressed to contain a more complete pipe system.

SUBJECT: Draft SOI Recycled Water Analysis

Executive Summary

This recycled water infrastructure analysis provides a discussion and summary of the anticipated recycled water infrastructure needs to serve the Folsom Sphere of Influence (SOI). Potential recycled water demands in the Folsom service area and SOI area have been investigated previously by Folsom, Sacramento Regional County Sanitation District (SRCSD), and El Dorado Irrigation District (EID). This analysis estimates total potential recycled water demands assuming full residential irrigation, parks, schools, office parks, commercial, and streetscapes for comparison purposes, as shown in Table 1. Results indicate demands are projected up to 7,700 AF per year, depending on extent of recycled water use and irrigation factors assumed.

Table 1. Recycled Water Demand Comparison

Study	Projected Annual Recycled Water Demands, AF
This Analysis

Targeted demands[b]	706
Draft SRCSD East County Feasibility Study[c]	
Folsom SOI C	1,947
Folsom SOI C ½	5,404
Folsom SOI D	7,708
Draft City of Folsom Water Recycling Feasibility Study[d]	
Alt 1	4,329
LO 5-4b	7,709

[a]Full potential demands include residential irrigation, parks, schools, office parks, commercial, and streetscape.
[b]Targeted demands include parks and schools in central and west side of SOI, and any irrigation of any commercial, businees, park, or streetscape adjacent to transmission mains.
[c]Draft SRCSD East County Feasibility Study data based on pdf from Jose Ramirez of the Sacramento Regional County Sanitation District via email dated August 29, 2007.
[d]Brown and Caldwell. Draft City of Folsom Water Recycling Feasibility Study, December 2005.

A targeted demand scenario is developed to plan for a system that serves most of the major non-residential recycled water demands within reasonable infrastructure requirements. The scenario assumes recycled water will be used at most parks and schools and some commercial, business park and streetscapes. Selection is based on logical grouping of sites near each other and proposed recycled water pipeline alignments. Sites selected are located in the central and west side of the SOI where most parks and schools are located. The Targeted scenario recycled water demands are compared to the total potable water demands projected in the draft Water Infrastructure Plan (J. Crowley Group, October 2007) in Table 2.

Table 2. Water Demand and Recycled Water Demand Comparison

Draft Water Infrastructure Plan[a]	8,769	0.0	8,769
This Analysis	--	706	--
Total:	**8,769**	**706**	**8,063**

[a] Draft Water Infrastructure Plan (J. Crowley Group, October 2007)

This analysis does not investigate potential supply details or strategies. It is assumed supply will be provided from a satellite plant located on an interceptor sewer located west of the SOI and Folsom. Development of the necessary infrastructure assumes a booster pumping station on the west side of the SOI, a transmission main through the south portion of the SOI, and a storage tank located within the SOI near Placerville Road. Smaller distribution pipelines serve demand areas located away from the transmission mains. Sizing and design of the recycled water system requires set policies and standards that should be developed to further plan the system. The total cost for the recycled water system is estimated at $37 million dollars. This estimate includes the satellite treatment plant, but does not include the pumping station and pipeline required to deliver the flow to the SOI western boundary, as these elements could vary significantly depending on location.

This analysis quantifies the potential impact to potable water demands and the associated costs of a recycled water system. If the City would like to pursue implementing recycled water, further investigation is required to identify and develop supplies, define policy and design criteria, and coordinate with the SOI land owners, EID, and SRCSD.

Section 1 Introduction

This recycled water infrastructure analysis provides a discussion and summary of the anticipated recycled water infrastructure needs to serve the Folsom Sphere of Influence (SOI) area. The area is currently undeveloped and no public water supply or wastewater collection system exists in the area. The City of Folsom intends to annex the area and provide water, wastewater, and potentially, recycled water services, in addition to other City services, to the area. Additional infrastructure plans are developed under separate reports for water and wastewater infrastructure requirements in the SOI area. This recycled water infrastructure analysis will support discussions of recycled water use in the SOI area.

Section 2 Recycled Water Policy Assumptions

Many policy, operational, and design assumptions must be made to preliminarily size the infrastructure requirements. The following lists the assumptions made for this analysis. Should recycled water use be selected, the City will need to secure a supply and develop policy and design guidelines for the operations and design of the recycled water system.

- Supply is from a scalping plant downstream of Folsom. The analysis assumed a booster pumping station at the west side boundary of the SOI.
- Irrigation will be allowed from 9PM to 6AM to avoid potential contact with overspray or runoff.
- Flow will be pumped to a storage tank during the non-irrigation times of the day. Supply from the tank will meet daily irrigation demands.
- A portion of the SOI on the east side is in the El Dorado Irrigation District (EID) service area. EID requires all new development to include recycled water irrigation of parks, schools, streetscape, and residential. A separate analysis is underway to determine all water, recycled water, and wastewater infrastructure requirements for the EID service area.
- An earlier study (Draft City of Folsom Water Recycling Feasibility Study, Brown and Caldwell, December 2005) investigated various levels of recycled water use. Scenarios ranged from just parks and public landscapes to full residential landscape and toilet flushing in commercial and industrial land uses. This analysis assumes that recycled water will be used for irrigation at parks and schools in the central and west side of the SOI. In addition, all streetscape, commercial, and business park land uses along the recycled water pipelines will also be irrigated with recycled water. The potential demands of the full use scenario, with residential and commercial uses, are quantified for comparison purposes only.
- This analysis is based on the land use plan presented in the draft Water Infrastructure Plan (J. Crowley Group, October 2007).
- Daily storage is provided, but no seasonal storage is assumed.

Section 3 Recycled Water Demand Projections

The potential use of recycled water for outdoor irrigation for the proposed land use plan is evaluated in this section. Outdoor irrigation demands can be projected using two methodologies: Evapotranspiration (ETo)-based demands or historic data-based demands. The ETo method is based on a reference ETo and considers irrigation demand versus precipitation to determine total irrigation demand. The historic data-based demand method uses Folsom historical data and customer use analysis presented in the 2005 Urban Water Management Plan. Both methodologies are presented below and compared to select a standard basis for demand calculations.

3.1 ETo-Based Unit Demands

Landscape irrigation unit demands based on turf grass are used for projecting demands. It is assumed that most outdoor water use will irrigate turf grasses or similar water-demand plantings. ETo-based demands are calculated according to the methodology presented in *A Guide to Estimating Irrigation Water Needs of Landscape Plantings in California,* University of California Cooperative Extension and California Department of Water Resources, August 2000. Landscape water needs are estimated according to the following landscape water needs equation (modified to include precipitation):

(Equation 1) $$TWA = (ETo(k_s * k_d * k_{mc})/IE) - (P*IE)$$

where:
TWA = total water to apply.
P = precipitation.
ETo = reference evapotranspiration.
k_s = species factor (allowable range = 0.1-0.9, assumed 0.9 for turf grasses).
k_d = density factor (allowable range = 0.5-1.3, assumed 1.0 – no planting density impacts).
k_{mc} = microclimate factor (allowable range = 0.5-1.4, assumed 1.0 – no microclimate impacts).
IE = irrigation efficiency (normal range 0.65-0.90, assumed 75 percent, takes into account runoff, sprinkler efficiency, and percolation beyond root zone).

ETo data and irrigation demands are shown in Table 3. Data is presented for an average year (average precipitation) and a dry year with a return frequency of five percent. The assumptions noted for the irrigation demand equation represent a conservative (high end) estimate of water demands appropriate for this level of planning. Actual values may be less depending on type of landscape installed and irrigation system maintenance practices.

Note that ETo does not change with hydrology; it remains the same regardless of precipitation. Therefore irrigation demands in dry years represent a need to irrigate for more months compared to other years. As shown in Table 3, the dry year irrigation demand is 10 percent greater than the average year. Due to precipitation and weather patterns in the Sacramento Valley, irrigation demands during the summer months are relatively constant regardless of hydrologic year type. Only the normal year demands are carried forward throughout this analysis, as dry year demands do not influence infrastructure sizing.

Table 3. ETo-Based Irrigation Demands

Month	Precipitation[a], inches		ETo[b], inches	Irrigation Demand[c], inches	
	Average	Dry		Average	Dry
Jan	4.4	2.2	1.59	0	0.3

Annual Totals	**24.2**	**13.3**	**57.06**	**52.6**	**58.5**

[a] Folsom Dam Station, Western Regional Climate Center, 1955-1993. Dry year represents five percent return frequency.
[b] CIMIS, Fair Oaks Station No. 131. (April 1977-2005)
[c] See Equation 3-1 for calculation assumptions.

3.2 Historic Data-Based Unit Demands

The 2005 Urban Water Management Plan (UWMP) and parallel water demand analysis investigated unit water demands for each of Folsom's land use designations, as well as indoor and outdoor use. Water production records are compared with operating conditions and a range of land use unit water demands from other agencies in the region to derive indoor and outdoor unit water demands for Folsom. Results estimate the outdoor demand unit water factor at 4.0 acre-feet per acre per year.

3.3 Unit Demand Comparison

The average year ETo-based unit water demand is 52.6 inches per year, or 4.4 acre-feet per acre per year. The dry year ETo-based unit water demand is 4.9 acre-feet per acre per year. These values are larger than the UWMP value of 4.0 acre-feet per acre per year, and larger than unit water demands experienced by other recycled water utilities in the region, such as Roseville and EID. This analysis will use the outdoor irrigation unit water demands presented in the UWMP to remain consistent with the water demand projections used for all water demands. If recycled water use is selected for the SOI, further analysis of demands and comparison with similar application sites is warranted.

3.4 Design Flow Peaking Factors

Design flow peaking factors are used to convert average annual demands to design flows used for sizing infrastructure. The peaking factors are applied to annual demands to determine maximum day and peak hour demands. The peak hour demand factor considers irrigation timing and practices to determine the peak hour flow rate. Maximum day and peak hour design flow peaking factors in Table 4 are based on factors from Sacramento Regional County Sanitation District (SRCSD) as shown in the Draft City of Folsom Water Recycling

Feasibility Study (Brown and Caldwell, December 2005). The maximum day peaking factor represents the maximum day to average day demand ratio and the peak hour peaking factor represents the peak hour to maximum day demand ratio.

Table 4. Recycled Water Design Flow Peaking Factors

Demand Condition	Peaking factor
Maximum day	2.6
Peak hour	3.0

3.5 Projected Recycled Water Demands

Unit water demands are applied to projected land use area to identify total annual water demands. A net acre factor is used to convert total acreage to actual acreage with water demands. This acreage reduction accounts for non-water demand areas, such as right of ways or pavement. Table 5 presents these factors as well as a comparison of the recycled water demands per land use for full reuse implementation for an average hydrologic year using the ETo-based unit water demands and using the historic data-based unit water demands.

A second reduced demand projection is shown in Table 6. Targeted parcels to include are developed based on review of the land use plan, site elevations, and potential pipe routes. The potential alignment was established to serve all large parks and school sites in the central and west side of the SOI. Other demands such as commercial, office park, and streetscape (OSL) were added if they were close to the main pipe alignment. This analysis assumes that most OS land use parcels will be un-irrigated, natural landscapes, and that any water demands such as parking or entrance areas, is met with potable water. Table 6 provides a summary of the targeted demands used for this analysis; selected parcels are also identified later in this analysis in Figure 3. Although the ETo based demands are not used further in this analysis, they are shown for comparison purposes only.

Table 5. Potential Recycle Water Demands for Full Implementation – Average Year

Total	**286**	**776**	**706**	**1.8**	**1.6**	**3,754**	**3,413**

[a]Recycled water to parks and schools in Zones SOI 2 and SOI 3 and any adjacent commercial and landscaped open space are assumed to be served.
[b]An unaccounted water use factor of 1.1 is applied to all demands.
[c]Acreage for OSL served is approximated based on estimated length of recycled water transmission pipeline multiplied by 20 feet width of landscape along the alignment.

Table 7 provides a comparison of SOI recycled water demand estimates in this technical memorandum and in previous studies. The total potential recycled water demand in this technical memorandum falls within the median of the estimates calculated in the SRCSD and Brown and Caldwell studies. Reasons for differences in irrigated acreages and recycled water demands between the previous studies could be due to varying unit water use assumptions and the SOI land use plan status at the time of each study. The actual demands used in this analysis are significantly less, at 706 acre-feet/year, as this analysis limits reuse to some parks and schools and other parcels near the proposed pipeline alignments.

Demand values are calculated for each month to size infrastructure on maximum demand requirements. The annual irrigation demand curve from Table 3 is applied to the selected recycle demand (706 acre-feet/year) used in this analysis in Table 8.

Section 4 Recycled Water Supply

This section presents the previous efforts to identify potential recycled water supplies. Supply planning efforts by the SRCSD and (EID) are summarized with recommendations for potential supply integration strategies. The overall strategy is to obtain supply from a satellite wastewater treatment plant that scalps flow from one of the SRCWD interceptors, obtain excess supply from EID, or a combination of the two supplies. However, to size infrastructure, this analysis assumed all flow would come from a scalping plant downstream from Folsom. If reuse is selected for the SOI, a concerted effort is required to investigate and secure a supply.

4.1 Recycled Water Supply Requirements

Recycled water supply for landscape irrigation follows unique characteristics due to irrigation demand patterns over a year. Demands vary by month, with the summer months using most of the supply, and the winter months using none. However, supply needs might not directly mirror demand needs as system operation and maintenance requirements also impact supply needs. For instance, during months of minimum demand, the system still must be operated so that irrigation water is available within the design pressure and flow parameters. Also, Folsom may choose to keep the system in full operation during periods of no theoretical demands (mostly winter), as some winters may still require irrigation due to low precipitation. During these times, the system may experience water age problems, such as algae growth. The system may need additional disinfection or may need to be flushed to keep the water quality within design parameters.

Due to climate patterns in the Sacramento Valley, where there is almost no precipitation during summer months, the maximum demand is during summer months. Maximum demand usually remains constant over many days. Peak hour demands are dependent on irrigation schedules. Other recycled water systems limit irrigation to night time hours. However, it one site sets the irrigation system to meet all of its demands in a two hour period, the site will exert a greater demand on the distribution system, impacting flow conditions at other sites.

The daily issues presented mostly impact design criteria, as recycled water systems are sized to meet the maximum day and peak hour demands. Annual issues such as minimum system operations and year-round availability affect the annual supply needs presented in this document. This presents a slightly different operation than other recycled water utilities in the region, as the others do not operate satellite systems, but simply make water available from their wastewater treatment plants or raw water systems as necessary. These supply issues will need to be further defined if recycled water use is pursued.

4.2 Folsom Wastewater Flows

The City of Folsom owns and operates its own wastewater collection system. Collected flows are discharged to the SRCSD interceptor system, and are then conveyed and treated by SRCSD.

A potential source of supply is to use the City of Folsom wastewater flows in a satellite treatment facility, or scalping plant. All flows from Folsom would be available as a supply source for the SOI recycled water needs. SRCSD has investigated this alternative in their Recycled Water Opportunities Investigation, November 2006. Of main concern in the SRCSD study is to ensure there is sufficient flow to meet minimum flow requirements in the interceptor downstream of the satellite plant.

The City of Folsom projects ultimate dry weather base flows in the ongoing update to the wastewater master plan at 11.0 mgd (email from ECO:LOGIC, November 9, 2007). This converts to an annual flow volume of 12,300 acre-feet. Wastewater flow projections for the SOI area are reported in the Draft SOI Wastewater Infrastructure Analysis (J. Crowley Group, October 2007). The two flows are combined to represent total flow from Folsom that could potentially be used for recycled water supply shown in Table 9. Flow projections do not include the Aerojet development of Easton Glenborough.

Flows reported are dry weather base flow estimates. Actual flows will be larger due to some groundwater infiltration and rainfall induced infiltration and inflow. However, for recycled water supply planning purposes, the base flow is used to provide the minimum projected supply. Total Folsom flows projected in the SRCSD Recycled Water Opportunities Investigation were not available for comparison.

Table 9. Total Folsom Wastewater Production at Buildout

Area	Daily Dry Weather Base Flow, mgd	Annual Base Flow, acre-feet/year
Existing Folsom Service Area[a]	11.0	12,300
SOI[b]	5.2	5,800
Total:	**16.2**	**18,100**

[b]Draft SOI Wastewater Infrastructure Plan, J Crowley Group, October 2007.

4.3 Supply to Demand Comparison

Daily supply must be able to meet maximum day demand because no seasonal storage is assumed. The maximum day demands are calculated for the range of demand scenarios from this and other studies discussed above. Annual demand is compared to supply on Figure 1. Maximum day demand is compared to daily supply on Figure 2. As indicated, when only using the wastewater generated by Folsom, there is sufficient supply on an annual basis for all of the demand scenarios listed. However, when looking at available supply on a daily basis in Figure 2, demand is much closer to supply. The supply numbers do not include the minimum pipe flow requirements suggested by SRCSD, which would result in even less supply. As the highest reuse demands occur at the lowest wastewater flow periods (summer), seasonal recycled water storage would help alleviate supply issues. Further coordination with SRCSD regarding minimum pipe flows and other supply issues is required to better define supply requirements.

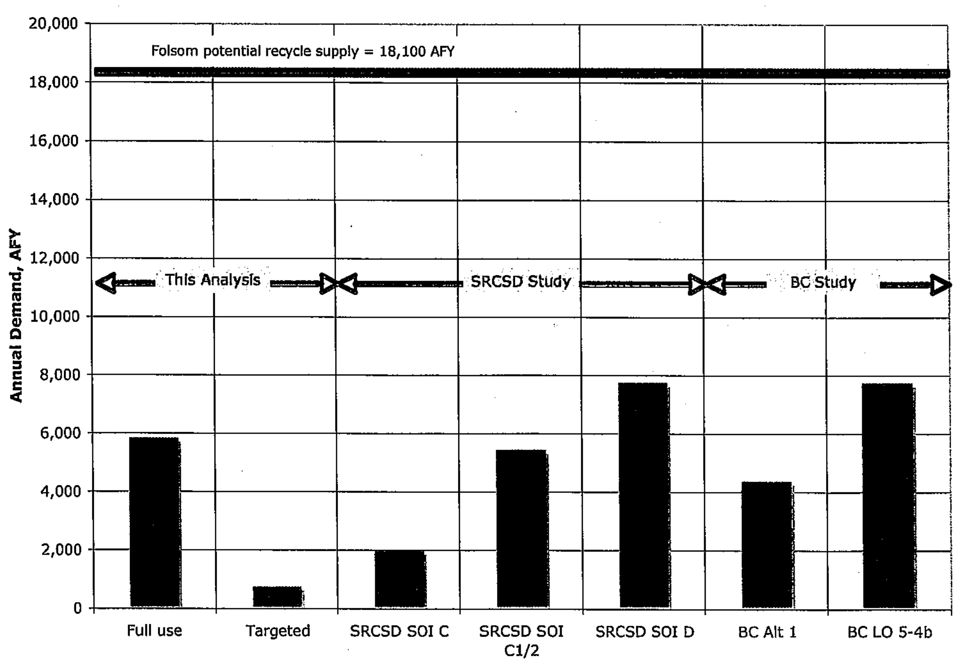

Figure 1. Annual Supply to Demand Comparison

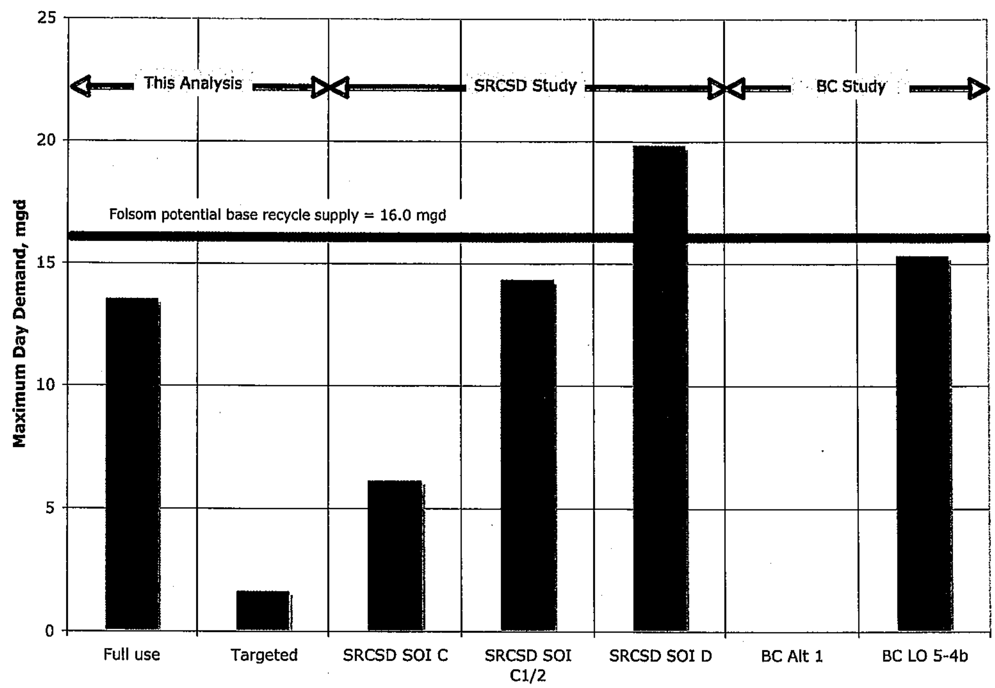

Note: BC Alt 1 did not project maximum day demands.

Figure 2. Maximum Day Demand - Supply to Demand Comparison

4.4 SRCSD Recycled Water Planning Effort Update

SRCSD released the Water Recycling Opportunities Study in February, 2007. Since that time, SRCSD continued to update is planning projections for the Highway 50 corridor recycled water alternatives. Additional efforts by SRCSD have further defined their supply and operational issues and policies. The available supply from a satellite treatment facility per the SRCSD planning efforts is not available at this time.

4.5 EID Recycled Water Planning Efforts.

EID produced the Draft Recycled Water Master Plan in December, 2002. The document identified a potential excess recycled water supply available for use in Folsom. Since that time, EID has revised its supply and demand estimates internally, and Folsom evaluated potential supply from EID in its December 2005 Water Recycling Feasibility Study. EID staff was contacted during this planning effort to update potential supply estimates, identify interest in supply collaboration, and identify other issues that may impact recycled water planning with EID. EID staff is unable to provide comment until their internal planning and analysis is further updated.

4.6 Glenborough/Easton Development

The Glenborough/Easton development directly east of the SOI area on Aerojet property also may use recycled water for some of its landscape irrigation needs. Projected wastewater flows from its area may be available as part of the overall supply. The SRCSD planning efforts assumed that the development would use recycled water, and routed the supply main through the development.

4.7 Recycled Water Supply Summary

Recycled water supply is available to the SOI from different alternatives. A satellite treatment plant could be located within the SOI, existing City of Folsom, Glenborough development, or further west as assumed in the SRCSD studies. Supply discussions with EID are preliminary. EID is currently unable to comment on available supply until they have more information from their ongoing recycled water supply studies and projects. This analysis assumes a satellite plant would be located west of the SOI.

Section 5 SOI Recycled Water Distribution System

This section develops alternatives for the recycled water distribution system within the SOI area. The internal distribution system is first developed with consideration to demand locations, main pipe alignments, storage needs and locations, pressure zones, and pumping requirements.

An extended period simulation hydraulic model of the SOI system was developed in this analysis using MWSoft's Infowater software, the GIS-based version of H2ONet. The development of a computer hydraulic model makes it possible to analyze the expected system performance at varying demand conditions such as maximum day and peak hour. System demands are assigned to specific nodes throughout the SOI.

5.1 Demand Assignment

Demands developed in this technical memorandum are grouped together and assigned to node locations as shown on Figure 3. The distribution main alignment was based on serving all schools and parks within water pressure Zones SOI 2 and SOI 3. Some of the commercial and business park demands will be served if the site is located along the recycled water main alignment. The SOI land use plan is used to identify all commercial and business park demands adjacent to the proposed recycled water main. The hatched parcels on Figure 3 are the school, park, and adjacent commercial and business park parcels being served recycled water in this analysis.

5.2 Supply Location

For this analysis it is assumed that the recycled water supply booster pump station is located in the northwest corner of the SOI, as shown on Figure 3. An analysis of the supply or a portion of the supply coming from EID is not included in this report.

5.3 System Development

A distribution system consisting of storage, booster pumping, and transmission mains was developed and input into the model. Sizing and modeling assumptions used to create the system are summarized in Table 10. These design criteria should be reviewed and further developed by the City during the SOI recycled water pre-design process. A 10 psi pressure differential between potable and recycled water systems is desired so that in the case of a system leak, the potable water system is at the higher pressure.

Figure 3.

Recycled Water Demands by Node

C:\Clients\City of Folsom\010-003 Folsom SOI\Recycled Water\Model\figures for TM 120607

Table 10. Sizing and Modeling Assumptions

Element	Value
Diurnal Storage	Volume equal to: One maximum day demand plus 50% of maximum day demand for emergency
Pressure range	30 psi – 70 psi
Pipeline velocity	3 to 5 feet per second maximum
Pipeline roughness coefficient	130
Minimum transmission main diameter	8-in

5.4 Diurnal demand

A diurnal time pattern was established to simulate system demands over a 24-hour period. The time pattern used in this extended period analysis is illustrated on Figure 4. For this analysis it is assumed that the recycled water use will occur between 9 PM to 6 AM to reduce the chance of public exposure to recycled water spray and mist.

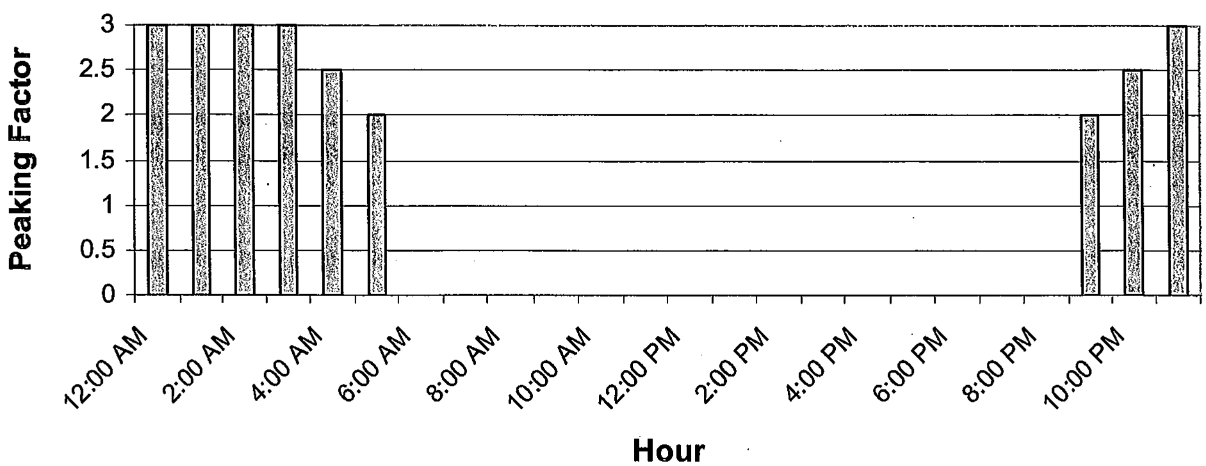

Figure 4. Diurnal Demand Curve for 24-Hour Maximum Day Period

5.5 Diurnal Storage

Diurnal storage must be provided so that the recycled water treatment facility can operate near a constant rate to maximize treatment stability. For this analysis it is assumed that the storage will be filled during non-irrigation hours (6 AM to 9 PM). The diurnal storage is sized to provide the supply for the night time demand as well as one half maximum demand day of emergency storage as shown in Table 11. Diurnal storage is typically provided in above-grade coated steel water storage tanks, designed similar to tanks used for potable water supply systems. The storage tank is located at an elevation of 500 feet in the Zone SOI 4 area.

Table 11. Storage Facility

Storage Requirement	Volume, MG
Maximum day supply	1.6
Emergency	0.8
Total	2.5

5.6 Pressure Zones

A one pressure zone recycled water system for the demand locations provides adequate pressures during the night-time demand period. During periods of no customer demand (between 6AM and 9PM) nodal pressures near the recycled water supply booster pump station are elevated as high as 170 psi. This high pressure is due to the required discharge head of the supply booster pump station necessary to pump recycled water to the diurnal storage facility. Another option is to place an in-line booster pump station and bypass valve along the alignment near the zone break between water pressure zones SOI 2 and SOI 3. This would reduce day time system pressures near the recycled water supply facility by reducing the required discharge head at the recycled water supply facility. Development of actual pressure zone boundaries and other details depend on as-yet undetermined operational policies and should be refined in the preliminary design phase.

5.7 Booster Pump Station

The booster pump station from the recycled water supply is sized to pump maximum day demands from the scalping plant to the storage tank during non-irrigation times. The capacity and horsepower for this booster pump station is provided in Table 12.

The horsepower (HP) required for this booster pump station is calculated based on the following equation:

(Equation 2) $$\text{Required horsepower}=Q*TDH/(eff*3{,}960)$$

Where:
Q = required flow, gpm
TDH = total dynamic head, ft
eff = pump efficiency, assumed to be 0.75

Table 12. Booster Pump Station Capacity

Booster Pump Station	Capacity	Horsepower
At supply scalping plant	2,000 gpm	250 HP

5.8 Transmission Mains

The transmission mains are sized for a pipeline velocity of 3 to 5 fps under peak hour demand conditions. Some 8-in pipelines have velocities lower than 3 fps, but for this technical memorandum a minimum pipe size of 8-in is maintained. Because this system has source supply coming from the west side of the system and the storage on the east side of the system, some of the pipelines will exhibit lower velocities during different times of the day. For example, the pipelines near the west side of the system are sized to convey supply from the scalping plant to the storage facility during the day time. When the pipelines are used to deliver supply to the irrigation sites, the velocities are much lower. The pipeline diameters and respective lengths are shown in Table 13 and illustrated on Figure 5.

Table 13. Transmission Main Diameters and Length

Diameter, in	Length, ft
8	4,754
12	14,812
16	9,227
Total (rounded)	**28,800**

5.9 SOI Recycled Water Distribution System Summary

The proposed system is shown on Figure 5. The pressures and velocities are shown for peak hour demands. High pressures occur on the west side during the non-irrigation hours when the booster pump station is pumping recycled water from the scalping plant to the storage tank. Pressure zone design depends on operational policies and will be addressed during the detailed planning and design phases.

Section 6 SOI Recycled Water Distribution System Cost Estimate

The estimated construction cost of the recycled water infrastructure is developed at a conceptual level in this section.

6.1 Unit Costs

Table 14 provides a summary of the unit cost assumptions for this conceptual cost estimate. Also provided are the references and/or assumptions used to estimate the unit costs. The cost estimates are based on using construction unit costs of similar facilities when possible. When such costs are not available, construction costs are estimated from available cost curves or other assumptions.

Table 14. Unit Cost Assumptions

Infrastructure Component	Unit Cost	Reference/assumption
Pipeline	$18/in-dia/linear foot	Based on recent bid tabs and completed construction for projects for local water agencies.
Booster pump station	$250/gpm	Treated water. Based on construction costs of service water pumping stations cost curve (Robert L. Sanks, Pumping Station Design, 1989, Figure 29-6) and based on recent project costs for Sacramento area booster station projected to January 2007.
Water storage tank	$0.50/gallon	Based on discussions with local contractors and water agencies on recent reservoir construction with foundation and appurtenances.
Recycled Water treatment facility (scalping plant)	$10/gallon	Based on high range of SRCSD estimate.

6.2 Construction Cost Contingency

Because of limitations of planning-level costs estimates, allowances must be made for variations in final length and depth of pipelines and other structures, adverse construction conditions, and other unforeseeable difficulties that may impact the final construction cost. A contingency allowance of 30 percent of the estimated construction contract cost is applied for this analysis.

6.3 Conceptual Construction Cost

The infrastructure requirements and conceptual level costs for are provided in Table 15. These conceptual level cost estimates are considered to be a planning level estimate for the purposes of comparing infrastructure options. This estimate includes the satellite treatment plant, but does not include the pumping station and pipeline required to deliver the flow to the SOI western boundary, as these elements could vary significantly depending on location. The cost of operations and maintenance for each alternative is not included in this analysis. In addition, this conceptual cost estimate does not include project costs such as engineering, construction management, and administration costs.

Table 15. Conceptual Cost Estimate

Cost Item	Size/capacity		Unit cost, $		Pipe length, ft	Cost, $million
Recycled water scalping plant	2.0	mgd	10	gal	--	$20.0
Pipeline	8	inch	18	in-dia/lf	4,754	$0.7
	12	inch	18	in-dia/lf	14,812	$3.2
	16	inch	18	in-dia/lf	9,227	$2.7
Booster pumping station	2,000	gpm	250	gpm	--	$0.5
Diurnal storage	2.5	MG	0.5	gal	--	$1.3
				Construction cost subtotal		$28.4
				Contingency (30%)		$8.5
				Total		**$37.0**

Note: Potential costs for pumping station and pipeline from scalping plant to SOI area not included.

Section 7 Summary and Next Steps

This draft technical memorandum presents the analysis findings as of this date. Coordination continues with the other SOI-related projects and with neighboring agencies. The following lists items to address next as the environmental review process moves forward.

1. Folsom and other stakeholders to review draft technical memorandum and provide edits and comments for refining next steps.
2. Continue coordination with EID to develop service scenarios for the east side of the SOI. Update analysis or prepare a separate plan once alternative is selected and agreed upon.
3. Coordinate review of draft report with environmental report efforts and modify analysis as necessary.
4. Update recycled water supply information as SRCSD and EID continue/complete their analysis.
5. In future pre-design phase, City of Folsom should develop recycled water system operational policies and design criteria.
6. Further analyze scalping plant supply location and impacts to on-site and off-site cost.
7. Sizing criteria should be further investigated by surveying other applications supplied by satellite plants to determine operational issues and associated impacts on infrastructure sizing.

Ground Water and the Rural Homeowner

Cover photograph: Rural dug well.

Ground Water and the Rural Homeowner

by Roger M. Waller

Preface

As the salesmen sang in the musical *The Music Man*, "You gotta know the territory." This saying is also true when planning to buy or build a house. Learn as much as possible about the land, the water supply, and the septic system of the house before buying or building. Do not just look at the construction aspects or the beauty of the home and surroundings. Be sure to consider the environmental conditions around and beneath the site as well. Try to visit the site under adverse conditions, such as during heavy rain or meltwater runoff, to observe the drainage characteristics, particularly the condition of the basement.

Many of the conditions discussed in this book, such as lowered well-water levels, flooded basements, and contamination from septic systems, are so common that rural families often have to deal with one or more of them. The purpose of this book is to awaken an interest in ground water and an awareness of where it is available, how it moves, how people can adjust to its patterns to avoid problems, and how it can be protected and used wisely.

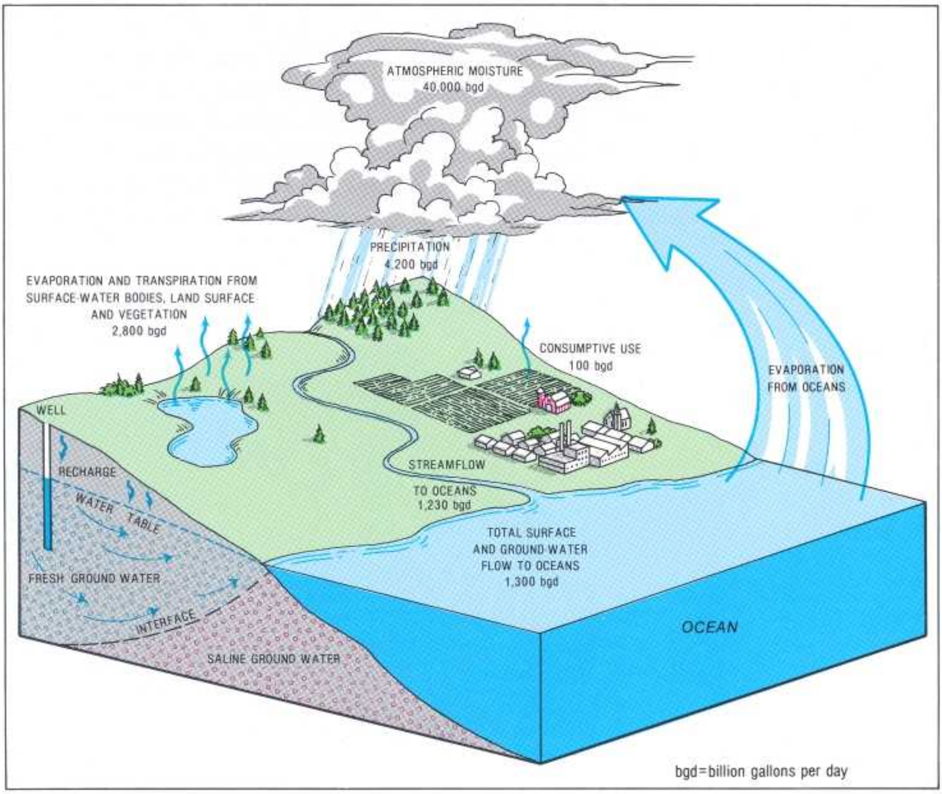
This booklet provides both present and prospective rural homeowners, particularly those in the glaciated northern parts of the United States, with a basic but comprehensive description of ground water. It also presents problems one may expect to encounter with ground water and some solutions or suggestions for help with these problems.

Introduction

When buying a home in the country, people need to consider certain factors that usually do not confront the urban homebuyer, such as whether or not the water supply is adequate and if the means of disposing of wastewater is safe. Disappointed rural homeowners have sometimes found out too late that the well drilled on their new land does not yield enough water or that the water is of poor chemical quality. Also, foundations can become unstable from excess surface runoff or from high ground-water levels. Septic systems, if not located properly or if soil conditions are not properly considered, can fail. Wells can be contaminated by septic systems or barnyard wastes. Shallow or dug wells on farms or near older homes that served adequately in earlier years are often inadequate for modern uses.

Preventing water problems or coping with them when buying or building a rural home can be either complex or relatively simple. Prospective homeowners need to know about the terrain, the proximity of the house to other structures, and the condition of the existing well and septic system. If building in an unpopulated area, drill a well first—or if buying an old house, find out if the water supply is adequate. This booklet describes the most common well problems encountered by rural homeowners, how to recognize them, solve them, or get help. But first, the characteristics and behavior of ground water and the relationship between ground water and the surrounding land are discussed briefly.

The Hydrologic Cycle

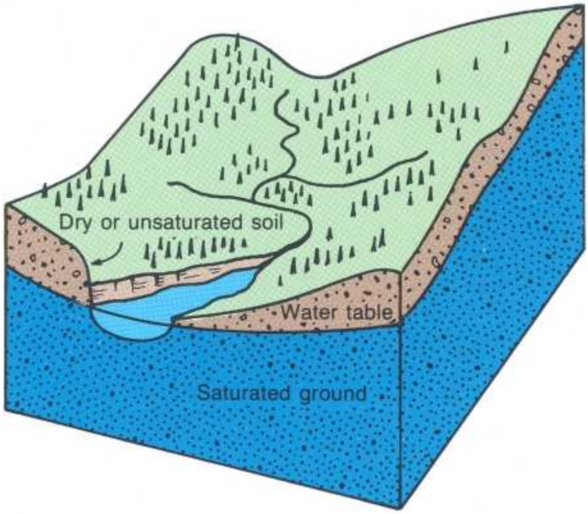


The continuous hydrologic cycle.

The hydrologic cycle is the continuous circulation of water from land and sea to the atmosphere and back again: water evaporates from oceans, lakes, and rivers into the atmosphere. This water later precipitates as rain or snow onto the land where it evaporates or runs off into streams and rivers; or it infiltrates (seeps) into the soil and rock from which some is transpired back into the atmosphere by plants. The remainder becomes ground water, which eventually seeps into streams or lakes from which it evaporates or flows to the oceans.

Ground Water

Ground water is that part of precipitation that infiltrates through the soil to the *water table*. The unsaturated material above the water table contains air and water in the spaces between the rock particles and supports vegetation. In the saturated zone below the water table, ground water fills in the spaces between rock particles and within bedrock fractures.



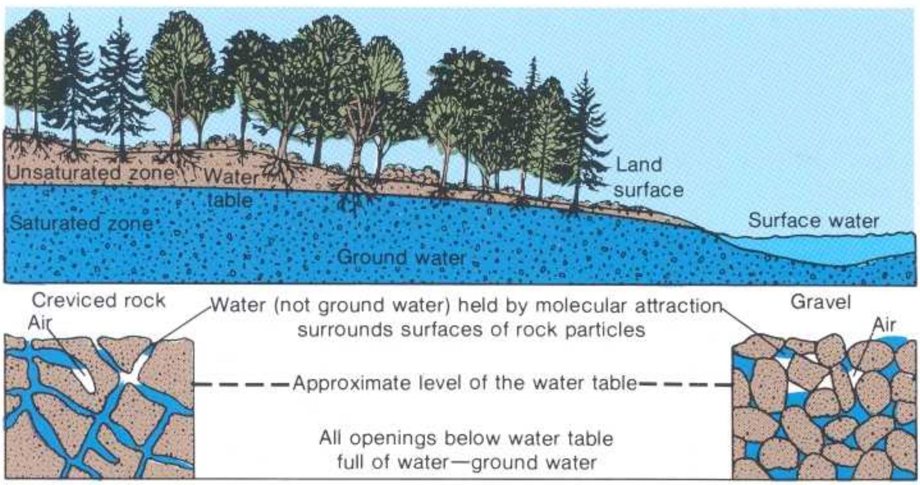
Occurrence of ground water.

Where ground water occurs

Rock materials may be classified as consolidated rock (often called bedrock) and may consist of sandstone, limestone, granite, and other rock, and as unconsolidated rock that consists of granular material such as sand, gravel, and clay. Two characteristics of all rocks that affect the presence and movement of ground water are *porosity* (size and amount of void spaces) and *permeability* (the relative ease with which water can move through spaces in the rock).

Consolidated rock may contain fractures, small cracks, pore spaces, spaces between layers, and solution openings, all of which are usually connected and can hold water. Bedded sedimentary rock contains spaces between layers that can transmit water great distances. Most bedrock contains vertical fractures that may intersect other fractures, enabling water to move from one layer to another. Water can dissolve carbonate rocks, such as limestone and dolomite, forming solution channels through which water can move both vertically and horizontally. Limestone caves are a good example of solution channels. Consolidated rock may be buried below many hundred feet of unconsolidated rock or may crop out at the land surface. Depending upon the size and number of connected openings, this bedrock may yield plentiful water to individual wells or be a poor water-bearing system.

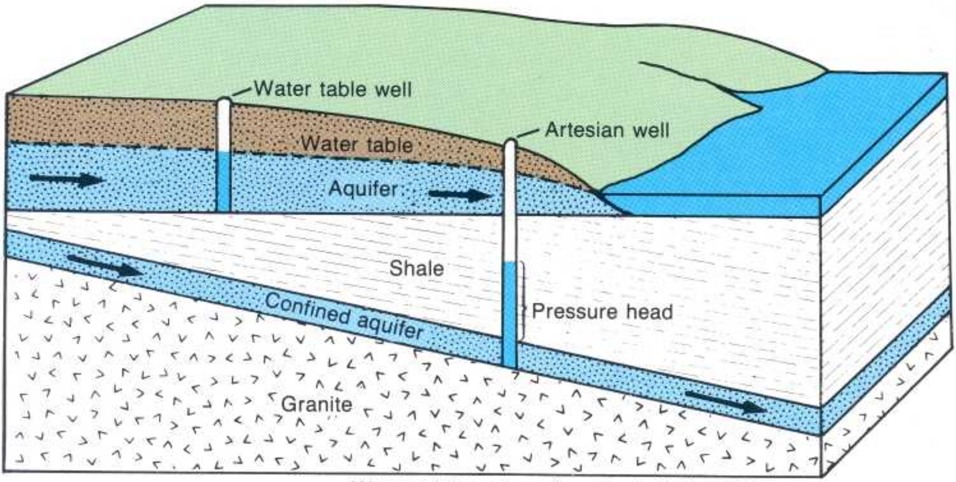
Unconsolidated material overlies bedrock and may consist of rock debris transported by glaciers or deposited by streams or deposited in lakes. It also may consist of weathered bedrock particles that form a loose granular or clay soil. Well-sorted unconsolidated material can store large quantites of ground water; the coarser materials—sand and gravel—readily yield water to wells.



How ground water occurs in rocks.

A close look at the rocks exposed in road cuts and along streams will show the types of openings in which ground water can occur. Especially noticeable in bedrock exposures are spaces between layers that can extend for miles—the void spaces between rock particles contain water that percolates into these spaces between the layers. In most sand and gravel deposits, water occupies and moves freely within granular material.

Road cuts reveal fractures, joints, and bedding planes.



Water-table and confined (artesian) aquifers.

Aquifers

Most of the void spaces in the rocks below the water table are filled with water. Wherever these water-bearing rocks readily transmit water to wells or springs, they are called *aquifers*.

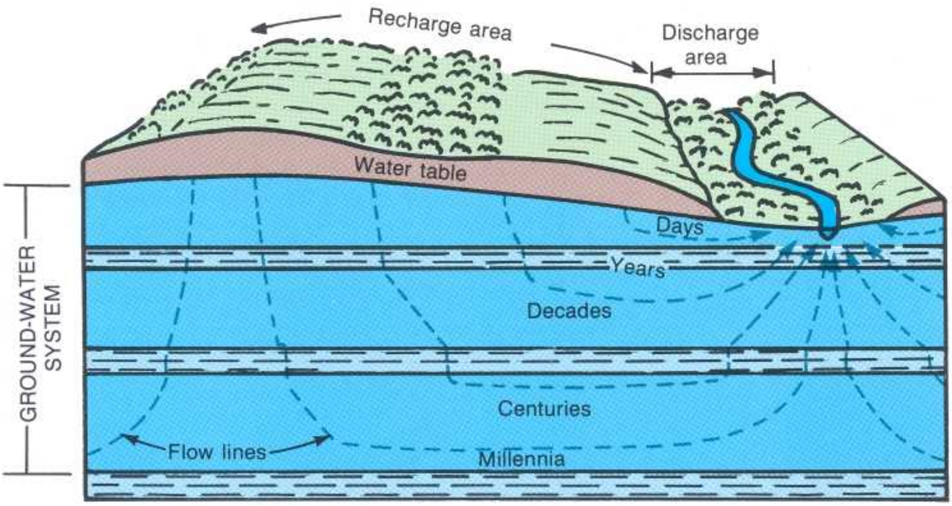
Although ground water can move from one aquifer into another, it generally follows the more permeable pathways within the individual aquifers from the point of recharge (areas where materials above the aquifer are permeable enough to permit infiltration of precipitation to the aquifer) to the point of discharge (areas at which the water table intersects the land surface and water leaves an aquifer by way of springs, streams, or lakes and wetlands). Where water moves beneath a layer of clay or other dense, low-permeability material, it is effectively confined, often under pressure. The pressure in most confined aquifers causes the water level in a well tapping the aquifer to rise above the top of the aquifer. Where the pressure is sufficient, the water may flow from a well.

Ground water is constantly moving

Ground water is always moving by the force of gravity from recharge areas to discharge areas. Ground-water movement in most areas is slow—a few feet per year. But, in more permeable zones, such as solution channels in limestone, movement can be as much as several feet per day. Evidence of the movement of ground water through rock and soil can be seen in road cuts, especially in winter, when the water freezes upon emerging from the rock. In some bedrock exposures, the water emerges along partings between rock layers; in others, along vertical fractures.

Seasonal patterns of ground-water recharge and storage

In latitudes where freezing is common, there is less recharge from rain or snowmelt during winter, which causes the water table to fall. Sporadic or differential freezing of the soil in the fall and winter inhibits recharge to the saturated zone, and the complete freezing of the soil in winter prevents all recharge until the soil thaws in the spring.



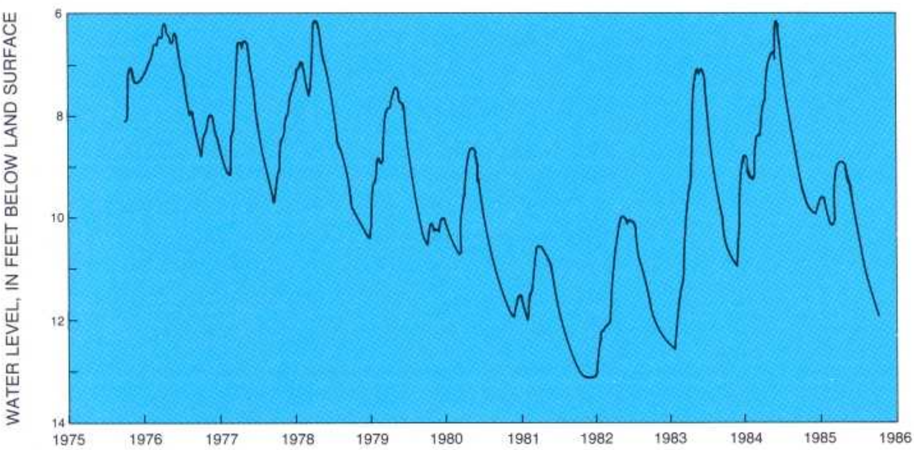
Direction and rate of ground-water movement.

Ground water, emerging from bedding planes, has created spectacular frozen waterfalls along a road cut.

The saturated zone beneath the water table is recharged by the excess water that is not discharged to streams. The resulting rise in the water table increases ground-water *storage* (the volume of ground water stored within an aquifer system). In late spring, summer, and early fall, evaporation and transpiration by plants capture most of the water that would otherwise recharge the aquifer, while discharge to streams continues. A seasonal decrease in ground-water storage results, as indicated by declining water levels in wells. In winter, freezing of the soil prevents recharge, which again causes a decline in storage. In early spring, frequent precipitation coupled with water from snowmelt causes a rapid increase in storage and a rise in the water table.

Effects of long-term climatic trends on ground-water storage

In addition to seasonal fluctuations in ground-water storage, long-term trends result from the variations in precipitation. Several years of below-normal precipitation causes a progressive decline in ground-water levels, and several years of above-normal precipitation causes a corresponding rise. These long-term climatic trends cause changes in ground-water storage. During periods of long-term, above-average precipitation, the water table may rise close to the land surface and interfere with home construction and waste disposal. For example, if a home had been built with a basement 8 feet below land surface during 1980-82 at the site of the well whose hydrograph is shown below, the basement would have been flooded in 1983 and 1984.

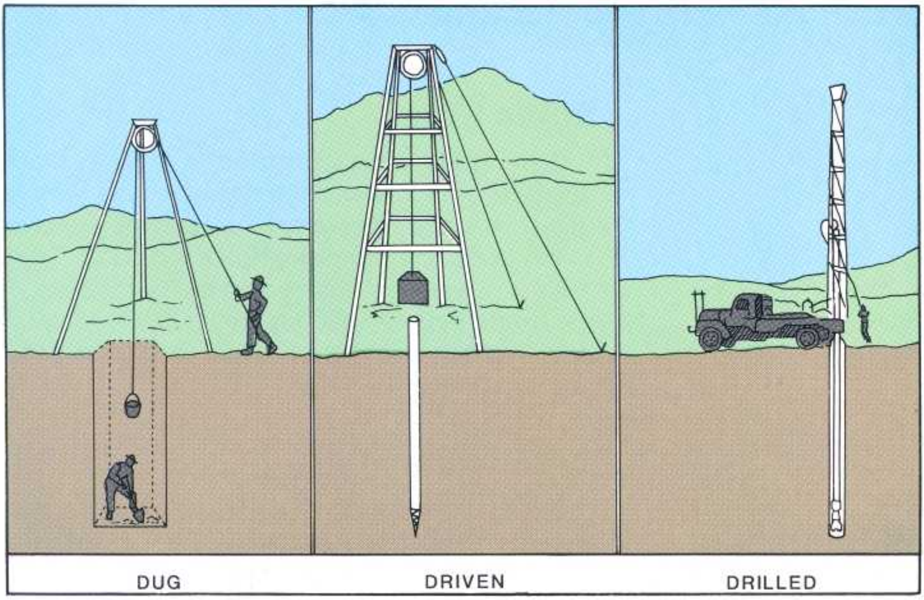


A 10-year well hydrograph showing climatic effects on ground-water level.

Types of Wells

Most modern wells are drilled by truck-mounted percussion (cable-tool) or rotary (air or hydraulic) drill rigs. Dug wells are still constructed in some areas, either by power equipment or by hand, but most hand-dug wells are the "relics" of older homes and were dug before drilling equipment was readily available or because drilling was considered too expensive. Driven wells, installed by hand or with power equipment, are still common and widely used where geologic conditions permit. Jetted and bored (augered) wells are less common types.

Types of wells.



Dug wells

Historically, dug wells were excavated by hand shovel to below the water table until incoming water exceeded the digger's bailing rate. The well was lined with stones, brick, tile, or other material to prevent collapse, and was covered with a cap of wood, stone, or concrete. Modern large-diameter dug wells are dug or bored by power equipment and typically are lined with concrete tile. Because of the type of construction, bored wells can go deeper beneath the water table than can hand-dug wells.

Dug and bored wells have a large diameter and expose a large area to the aquifer. These wells are able to obtain water from less-permeable materials such as very fine sand, silt, or clay. Some disadvantages of this type of well are that they are shallow and lack continuous casing, making them subject to contamination from nearby surface sources, and they go dry during periods of drought if the water table drops below the well bottom.

Driven wells

Driven wells are constructed by driving small-diameter pipe into shallow water-bearing sand or gravel. Usually a screened well point is attached to the bottom of the casing before driving. These wells are relatively simple and economical to construct, but they can tap only shallow water and, like dug wells, are easily contaminated from nearby surface sources.

Modern truck-mounted drill rig.

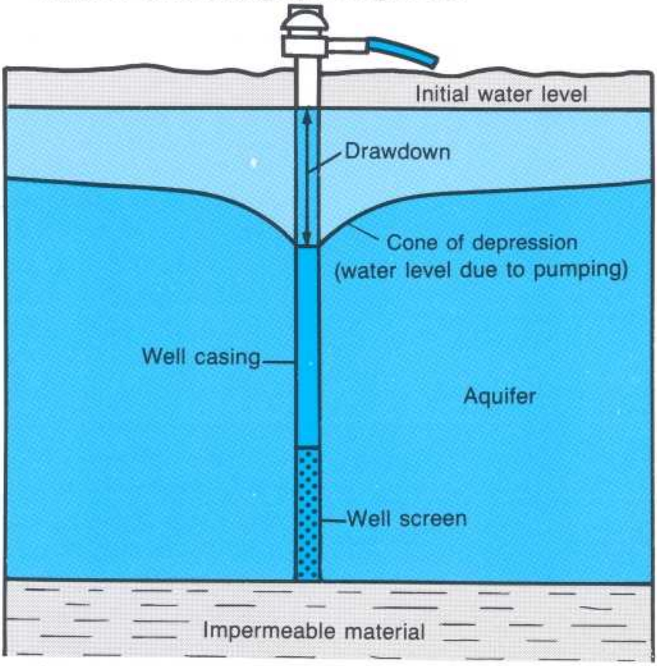
Drilled wells

Drilled wells are constructed by either percussion or rotary-drilling machines. Drilled wells that penetrate unconsolidated material require installation of casing and a screen to prevent inflow of sediment and collapse. They can be drilled more than 1,000 feet deep. To prevent contamination by water draining from the surface downward around the outside of the casing, the space around the casing must be sealed.

Wells and Pumpage

Even though water is present at some depth at almost any location, the success of obtaining an adequate domestic supply (usually 5 gallons per minute) of water from a well depends upon the permeability of the rock. Where permeable materials are near land surface, a shallow well may be adequate. Elsewhere, such as where clayey material directly overlies bedrock, a deep well extending into bedrock may be needed.

Pumping a well lowers the water level around the well to form a cone of depression in the water table. If the cone of depression extends to other nearby wells, the water level in those wells will be lowered. The cone develops in both shallow water-table and deeper confined-aquifer systems. In the deeper confined-aquifer system, the cone of depression is indicated by a decline in the pressure and the cone spreads over a much larger area than in a water-table system. For a given rate of withdrawal, the cone of depression extends deeper in low-yielding aquifers than in high-yielding ones.



Cone of depression caused by pumping.

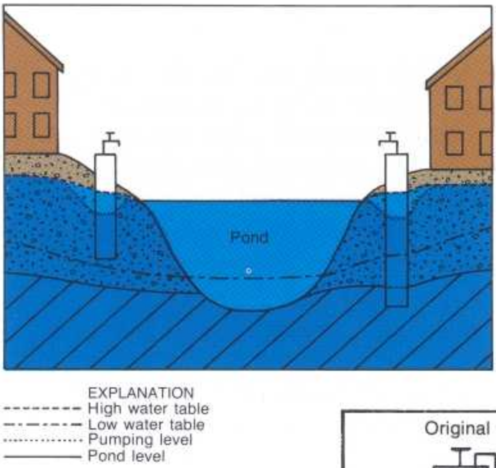
Water-Level Declines

The old saying that you "never miss the water until the well runs dry" remains true; however, *few drilled wells ever actually go dry*. Rather, what occurs most often is that the water table has dropped to near or below the pump intake because the pump intake is not set deep enough to allow for a potential decline in water levels. Alternatively, the small strainer that covers the end of the pump intake could be partly clogged so that it takes longer to pump the same amount of water. In either case, when the pumping rate exceeds inflow to the well, air is pumped and no more water is produced until the pump is shut off and the well recovers.

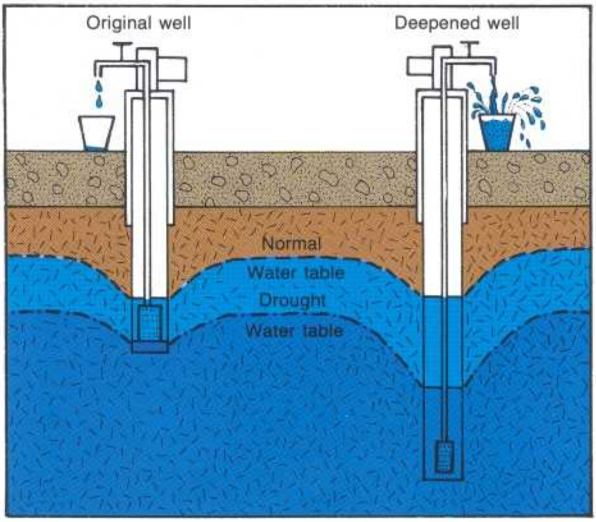
Shallow wells

The most common "dry well" problem has been with dug wells. Most dug wells are shallow and excavated in poorly permeable material; consequently they are readily affected by drought or by seasonal declines in the water table. The following figure shows the effect of declining water levels on two adjacent wells that are drilled to different depths on either side of a water-table pond. If the depth to water in the well on the left were, say, 10 feet during spring, it might decline to 15 feet during late summer or during a severe drought. If the pump normally causes the water level in the well to decline 5 feet or more during a pumping cycle, pumping during the drought would cause the water to decline to or below the pump intake. Excavating this well deeper to match the well on the right would solve this problem. Dug wells should be constructed during seasonal or climatically low-water-level periods.

Many dug wells extend only to the bedrock surface and tap the perched water (unconfined ground water separated from an underlying main body of ground water (aquifer) by an unsaturated (impermeable) zone) on top of the bedrock. These wells cannot be easily deepened. In such cases a new drilled well is the only long-term solution.



How does a well go dry?

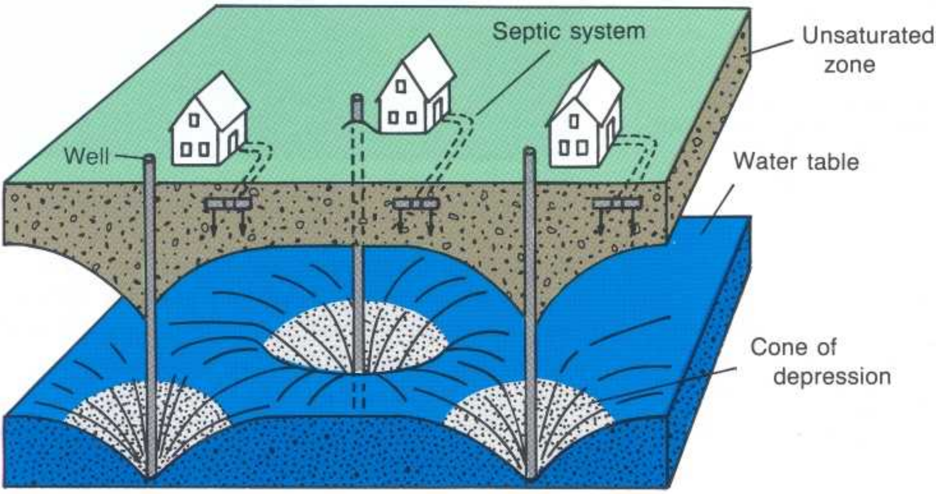


Solving a drought-related water shortage by deepening the well.

Some drilled wells that tap shallow bedrock will yield only 1 or 2 gallons of water per minute. These wells are not deep enough to provide adequate storage of water for short-term pumping cycles. Such a well may contain only 50 feet of water above the pump intake. As an example, when the water table declines 10 feet because of drought conditions, only 40 feet of water is available in the well for one pumping cycle, and the well seems to "go dry." In that situation, deepening the well may solve the problem as long as the deeper water is of good quality. If usable water is not available at a greater depth, the pumping rate must be reduced so that less water is pumped during each cycle.

Increased pumping in the immediate area

Another reason that wells "go dry" is the lowering of the water table by increased pumpage in the immediate area. Housing developments with small lots and individual wells have been built in many rural areas. If the aquifer is low yielding so that pumping causes a large drawdown, a cone of depression will develop around each well. Thus, several domestic wells close together can create a steady lowering of the water table if pumpage exceeds the natural recharge to the system (unless the withdrawn water is returned to the aquifer through septic systems). A third major reason that rural wells "go dry" is the installation of larger capacity wells for municipal, industrial, or agricultural purposes adjacent to residental areas. The increased withdrawals may cause large widespread cones of depression that intersect one another and cause general water-level declines that affect nearby domestic wells.



Effect of concentrated housing on ground-water level.

Water-Level Rises

The opposite problem, namely a rising water table, has developed in some parts of the country. Rising water tables occur in areas where pumpage has been curtailed after years of large ground-water withdrawals, such as for mine dewatering or municipal water supply, which kept the water table below its natural levels. The curtailment of pumping allows the water table to rise to the previous natural level, which may flood underground structures that were built when the water table was lowered.

In many parts of the country, water levels in shallow aquifers have been lowered artificially over large areas. If houses are constructed in dewatered areas and if the water table then recovers to its natural (higher) level, basement flooding or foundation failures may occur, especially where the natural water level is within 10 feet of the land surface. Many basements that were built in a dry unconsolidated material and that had remained dry for decades have now become permanently wet. The public's first reaction may be that unusually heavy precipitation in the past few months has raised the water table or created a temporary perched-water system, when in fact the situation is much more serious and will remain a problem unless pumping is resumed to maintain a lower water table.

Where water levels are closely monitored, water-level records can indicate whether such high water levels are related solely to climatic events or whether water levels are recovering after nearby pumping has ceased. An increasing number of local areas are being dewatered for mining or industrial uses, which could cause serious problems in the future when such pumpage is decreased or ended.

Similar situations have occurred where housing developments were built during a period of extended drought when the water table was low. Even if basements were the "daylight" or raised type because the natural water table was shallow, the eventual return of a wet period caused the water table to rise a few feet and flood basements.

Quality of Water

Some common ground-water quality concerns are excessive hardness (high dissolved magnesium and calcium content), a high concentration of salt or iron, or the presence of hydrogen sulfide (sulfur), methane gas, petroleum or organic compounds, or bacteria. Some are naturally occurring; others are introduced by human activities. In many areas, the homeowner has little recourse other than to use chemical treatment to remove or reduce the level of these constituents or to abandon the water supply. Hardness, iron, and sulfur are common constituents that can be treated.

Salt contamination

Salt contamination is difficult and expensive to remedy unless the well drawing saline water from a deep aquifer also penetrates one or more freshwater aquifers at lesser depth. In such cases, the deep saline aquifer can be sealed off and the well can be drilled in the freshwater aquifer instead. In many parts of the country, however, when a well is drilled deeper into bedrock to obtain larger supplies, saline water is more likely encountered than additional freshwater is.

Road-salt contamination of ground water has increased in the last 30 years and is of major concern in northern areas. Highway departments mix salt with sand to spread on roads for deicing. Salt is readily soluble in water and runs off highways into lakes and streams and percolates to the water table.

Probably more serious than the spreading is the stockpiling of uncovered salt and sand mixtures. This practice produces concentrated saltwater runoff that percolates to underlying aquifers and nearby wells. Many stockpiles are within small villages or near housing areas where nearby domestic wells can become contaminated.

Leachate from sand and salt stockpiles is a potential source of contamination to shallow ground water.

Oil spills

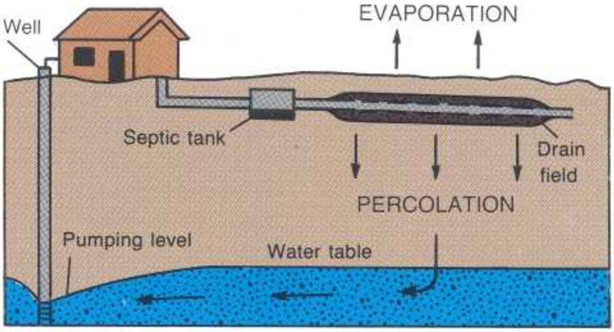
Another chronic problem in many rural homes is leaking or spilled fuel oil which eventually contaminates the owner's own well. Many homes have a fuel tank, either buried or above ground, adjacent to the house and within a few feet of the well. Spills or accumulated leakage eventually can migrate to the aquifer and can be drawn into the well, making it unusable for years. Usually the only solution is to obtain a new water source. In some instances, however, reducing the pumping rate to reduce drawdown allows the oil to float on the water surface safely above the well's intake area.

Methane gas

Perhaps the problem that poses the greatest hazard to a well owner is flammable gas in the well. Small volumes of natural gas, usually methane, can be carried along with the water into wells tapping carbonate or shale rock. In some areas, the gas dissipates soon after installation of the well, but, in other areas, a large continual source of natural gas remains. Because methane is flammable and cannot be detected by smell, precautions are needed to prevent explosions and fire. Venting of the well head to the open air is the simplest precaution but, because gas can also accumulate in pump enclosures, pressure tanks, and basements, other venting may be needed. For this reason, a home should never be built over a well.

Bacteria

The most common water-quality problem in rural water supplies is bacterial contamination from septic-tank effluent. A recent nationwide survey by the U.S. Environmental Protection Agency and Cornell University found that contamination of drinking water by septic effluent may be one of the foremost water-quality problems in the Nation.



How septic effluent percolates to the water table.

Barnyard runoff

Probably the second most serious water-contamination problem in rural farm homes is from barnyard waste. If the barnyard is upslope from the well, barnyard waste that infiltrates to the aquifer may reach the well. Pumping, too, can cause migration of contaminants to the well. On many farmsteads built more than 100 years ago, the builders were careful to place the supply well upslope from the barnyard. Unfortunately, many present-day owners have not remembered this basic principle and have constructed a new house and well downslope of the barnyard.

Barnyard upslope from farmhouse well may cause bacterial contamination of water supply. *(Photograph courtesy Cornell University.)*

Pesticides and fertilizers

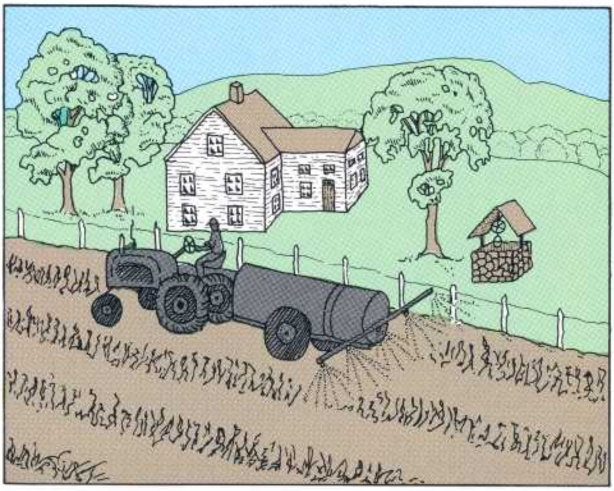
The last 3 decades have seen a significant increase in small part-time farms and rural dwellings as large farms have been sold and divided into smaller units. Many modern rural homes are constructed on former cropland on which heavy applications of herbicides and fertilizers may have been made. How these chemicals move

New home on land recently used for crops.

through the soil and ground water and how quickly they decompose or how their harmful effects are neutralized is not well understood.

Also common is the farming practice of applying fertilizers and pesticides to croplands immediately adjacent to the barnyard or farmyard. Residue from these applications can infiltrate to the aquifer and can be drawn into a supply well for the barn or the house. Decreasing the use of fertilizers and pesticides in the vicinity of wells can help minimize this problem.

Homeowners also should be careful to properly dispose of wastewater from used containers of toxic chemicals. Many farms have their own disposal sites, commonly pits or a wooded area, for garbage and the boxes, sacks, bottles, cans, and drums that contained chemicals. Unfortunately, these owner disposal sites can contaminate farm water supplies.



Pesticide spraying near well.

Septic Systems and Ground Water

The liquid effluent from a septic system follows the same path as the rain or snowmelt that percolates into the unsaturated zone. Like the rain, once the effluent reaches the water table, it flows down the hydraulic gradient, which may be roughly parallel to the slope of the land, to lower points. Thus, again, the location of one's house in relation to neighboring houses, both upslope and downslope, is important.

Septic-tank effluent that enters the aquifer supplying the homeowner's well introduces not only bacteria but also other contaminants. Many rural homeowners also discharge other waste products, including toxic material, into their septic systems, and these products gradually accumulate in the aquifer. What happens to these contaminants in the ground is not well known. Some adhere to rock material, others travel with the water. In some types of rock material, the leach field or dry-well part of the septic system can gradually become clogged by contaminants.

Rural homes in small, older communities and in more recent roadside housing developments are commonly situated on small or narrow lots along an access highway. Most do not have a

Rural roadside housing development.

community water supply, and almost all have their own individual septic systems. In clusters such as this, effluent recycling can occur if the wells are shallow or the septic systems are improperly placed. Deep wells are less likely to draw in septic waste.

This type of effluent problem becomes acute in an area underlain by a shallow water-table aquifer where the septic effluent discharges into water that is used by many homeowners. This dilemma has been posed in many rural housing developments throughout the Nation. One either "fouls his own nest" with effluent or connects to a central sewer system. Although a sewer system protects the aquifer from further contamination, it reduces recharge of water to the aquifer. This engineering, economic, and social dilemma must be resolved soon in many areas. An increasing number of counties and townships are planning and zoning rural areas to limit the density of houses according to soil conditions. Other approaches being considered are a community water supply with individual septic systems or individual water supplies with a community sewer system.

Some banks and lenders require that the prospective buyer or the seller furnish proof of a bacteria-free water supply before they will issue a mortgage. When a seller faces such a requirement, a common procedure is to chlorinate the water to destroy the bacteria in the well. This treatment affects only the well and perhaps a volume of the aquifer immediately adjacent to the well, but for only a brief time. If the contamination is in the aquifer, the source will not be attacked nor the problem solved; thus a water analysis showing bacteria-free water immediately after the well has been disinfected is not necessarily an assurance of a safe water supply. The homeowner should periodically have the water analyzed for bacteria. If a high bacteria count occurs repeatedly, the problem is probably in the water source, and chemical treatment of the well alone cannot solve it.

In a bacteria-contaminated water system, chlorination of the water pumped from the well is commonly recommended as a solution. Otherwise, one must obtain a water supply from a new well that either is upgradient from the contaminating source or that taps a deeper aquifer. Moving the septic system to a more distant spot is a long-term solution, but the underlying contaminated zone may take years to stop releasing contaminants to the aquifer.

Cluster-housing contamination

In a row-housing setting, the house at the highest location will generally have the safer water supply. Because the effluent migrates down beneath the development, it could be pumped, used, and again discharged by each house along its course. The house furthest downslope would receive the combined effluent from the other houses.

Another contamination problem from closely spaced septic systems can occur where a row of houses on the uphill side of a road faces a row of houses on the downhill side of the road. Here, the safer water supply would be on the uphill side. The downhill side would receive effluent from the uphill side plus any contamination generated along the road, such as road salt or metal compounds. In flat areas underlain by a shallow water table, especially where cluster developments are two or more decades old, almost perpetual recycling of septic waste may occur.

Another source of contamination that is common in villages or hamlets lacking a central water or sewage system is small waste-generating businesses such as laundries, auto-repair shops, and industries that discharge wastes to their own septic systems. Many of the bacterial problems, cited in a recent U.S. Environmental Protection Agency rural water study, were in hamlets, villages, or crossroads communities. Once indoor plumbing became common and outdoor privies were removed, all waste went into septic systems from which increased amounts of liquid effluent eventually entered the aquifer and became subject to pumping by wells.

Unknown Hazards Beneath the Land

Previous land uses, some of which may be unknown to the present landowner, can have long-lasting effects on the land and on underlying aquifers.

Hidden dump site may contain chemical-waste containers.

Former chemical dump sites

Many sites where commercial and industrial wastes are buried have been abandoned and have been covered with soil or have become revegetated. In many such areas, individual homes or entire housing developments have been built without proper consideration of the buried waste. (The tragedy of Love Canal, near Niagara Falls, N.Y., is an unfortunate example of construction over concealed waste.) A prospective land buyer, home builder, or buyer of a recently built rural home should inquire of local agencies about the former use of the land.

Abandoned wells

Although still relatively rare, waste sites can be abandoned wells that are now used for disposal of wastes, commonly oil or laundry wastes. Many garages and repair shops have used abandoned drilled wells for disposal of waste oil, and laundries have used abandoned dug wells for disposal of laundry wastes to prevent clogging of their septic systems. These practices point to an area where concern for ground-water protection should be considered more carefully. Abandoned wells should be filled and sealed properly to eliminate the danger of someone falling into the well or having the shaft collapse, as well as to remove the temptation to use them for disposal of hazardous wastes.

Former orchards or vegetable lands

Individual homes and developments alike have been built on former orchards or vegetable farms. Although these lands can be picturesque where fruit trees remain, one must remember that pesticides and chemical fertilizers probably were applied heavily in the past. The fate of many of these chemicals in the soil is unknown, and long-term contamination may remain, especially in the shallow ground water. The soil through which recharge from precipitation moves is the repository for much of the chemicals that are deposited on the land. Decades may pass before these chemicals are dissipated or flushed away. Therefore, anyone planning to buy or build a house on a former orchard or truck farm should consult farm or zoning agencies to obtain information on the potential for pesticide and fertilizer residue.

Crop dusting and orchard spraying. *(Photographs courtesy Cornell University.)*

Oil and gas fields

Oil and gas development has occurred and is occurring in many parts of the country. Oil and gas development almost always includes the production of brine or saline water, which then must be disposed of. Most states regulate the disposal of brine to prevent contamination of surface and ground water, but, in old oil and gas fields that were abandoned before extensive regulation, saline water is still escaping from improperly sealed or cased wells into freshwater aquifers.

One method of producing more oil or gas from old fields is to inject water or brine into the producing formation to increase the pressure and move the oil or gas to wells. Some oil or gas fields are "leaking," however, and once the pressure is increased, the injected fluid or oil finds avenues of escape to other formations, such as through abandoned boreholes or corroded well casings. Some shallow producing areas that contain many abandoned wells spaced a few hundred feet apart have created an unmanageable leakage problem. Every old abandoned oil or gas well that is not cemented-in may provide an avenue for saline water, oil, or gas to escape into the nearest aquifer and contaminate the system. It would be wise to verify that the home being purchased is not near an old oil or gas field.

Subsidence and sinkholes

Land subsidence occurs where large amounts of ground water have been withdrawn from a thick layer of saturated fine-grained sediment that is susceptible to compaction. General subsidence is not noticeable in some large areas, but in others, concentric cracks develop over smaller areas where compaction is occurring.

Sinkholes are common where the land is underlain by limestone or other carbonate rocks that are naturally dissolved through ground-water circulation. A sinkhole can also develop where salt beds occur beneath the land surface. As the limestone or salt is dissolved naturally by ground water or by industrial solution-mining of the salt, the overlying material can collapse into the resulting cavern. In worst cases, such collapses create a large sinkhole that will topple or swallow any structure above it. Housing development should be avoided in sinkhole-prone areas. Although it is difficult for an individual to discern the exact locations of potential sinkholes, areas prone to sinkhole development are generally well known by State geological surveys.

Sinking land ruins croplands.

Sinkholes develop suddenly.

Consider Past and Future Land Use

The preceding section highlighted some of the contamination hazards that may be attributed to previous land uses. One way to obtain information on previous land use is to contact local county or town planning or zoning boards. Their records may show that land was formerly used for agriculture, landfill, or industrial/mining purposes. Land owners can then better evalute what past land-use practices should be considered in planning future land use.

Similarly, land-use or zoning maps can show where planners have designated uses that may be considered detrimental to home ownership. Many planning agencies have evaluated and classified the land for preferred and alternate uses. Consult these local agencies before building or buying in specific areas.

Country Living Calls for Knowledge

Before purchasing a home in a rural area, the buyer should determine the amount and quality of water and should locate the waste-disposal system.

A well log and a water analysis may be as important as a deed

As ground water receives increasing attention nationwide, particularly because of toxic-chemical contamination, a written legal document verifying an adequate water supply from new or old wells is becoming important. Some mortgage lenders require a negative bacterial analysis of the water and a yield test of the well to verify an adequate supply. As mentioned earlier, a single analysis for bacteria may not reflect true conditions, but it is worthwhile to have it done nevertheless.

A well record (driller's log) describes the well characteristics, including yield and the type of material that the driller encountered. The well log is not always available from the owner, and sometimes the driller who installed the well cannot be located. If the well log is available, however, it can be helpful. If water quantity becomes insufficient, a record of a yield test is helpful in determining what happened. Most dug wells, of course, have no description other than depth. In any case, it is wise to obtain information on well depth, water level, type of pump, pump-intake setting, and yield before buying a house.

Determine the location of the septic system and water source

The buyer of rural property must know the location of the water source and the waste-disposal system to evaluate the potential for certain problems. Even a cursory glance at their location, distance from each other, and the land slope often provides an initial estimate as to their adequacy. For example, evidence of two or more wells or septic systems warrants a detailed inquiry. An odor of sewage, a wet area, or lush grass over a leach field, especially during dry periods, indicates a potential problem.

Some Practical Considerations

As stated earlier, learn as much as you can about the land, the water supply, and the septic system of the house before you buy. Be sure to consider the environmental conditions, and try also to visit the site during bad weather. Don't be rushed—take time to be informed.

Most rural water problems are related to old dug wells, septic systems, and too-dense housing developments. Drilled or deep wells are generally less susceptible to sewage or surface-contamination sources than shallow wells are, but water from bedrock wells is more likely to contain gas or minerals than is water from shallow deposits. Most well drillers are aware of common local problems and generally locate wells properly.

Although potential water problems for the rural homeowner can sometimes be expensive, pose a health hazard, or possibly affect real estate values, these problems can be avoided by the observant, informed buyer or owner.

Table 1. **Water factors to consider in buying or building a new home**

Problem	Probable cause	Remedy or source of help
Inadequate water yield	Poor aquifer	Install larger, deeper well
	Well screen or pump intake encrusted	Have cleaned by well driller
	Lower water level	Deepen well Contact water resources agency
Wet basement	Seasonally high water table	Add sump pump or drains
	Recovered water level	Add sump pump or drains
	Drainage from roof or slope	Add roof gutter, reslope land Contact Soil Conservation Service
Gas in water	Methane from bedrock	Install vent on well head Aerate the water Install water treatment Drill new well away from house Contact State geological survey
Salty water	Road salting	Install new well farther upslope Provide better road drainage
	Road-salt stockpile	Install new well away from drainage Request correction by highway department Contact health department
Fuel-oil contamination	Leaky or spilled storage tank	Install new well upslope Adjust to low pumping rate
Oil or gasoline contamination	Nearby service station	Obtain new source of water Contact health department
Bacteria contamination	Septic effluent	Chlorinate as first step; contact health department Install new well upslope Install new leach field farther away Deepen well in some cases Seek control on neighboring system
	Barnyard waste	Redirect waste flow Install new well upslope Seek control on neighbor's activity Contact agricultural agency
Organic chemical contamination	Former land use	Install new well farther away Deepen well in some cases Contact health department
	Current land application	Create buffer zone around recharge area Dispose of wash water properly Seek control on neighbor's activity Contact health department
Land Subsidence	Excessive ground-water withdrawal	Contact State regulatory agency
	Rock solution	Relocate house Contact State geological survey
Sinkhole development	Rock solution	Relocate house Contact State geological survey
Source of ground water unknown	No knowledge	Contact water resource agency
	No well data available	Contact water resource agency

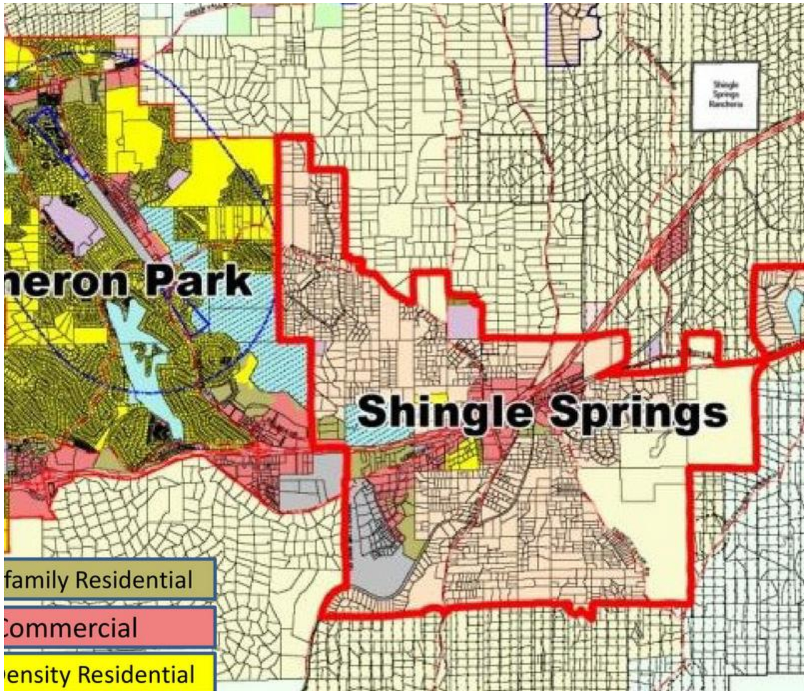
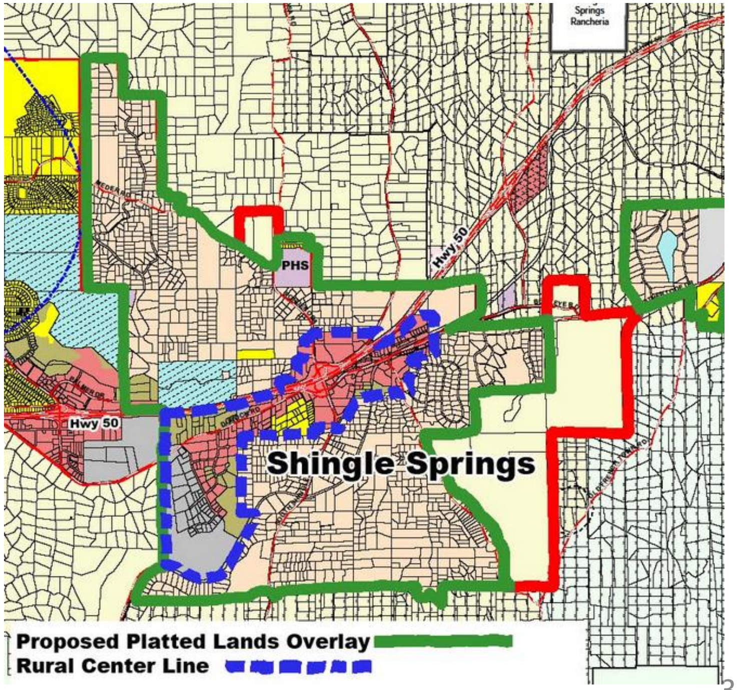
<u>SSCA</u> supported the **December 9, 2014** vote by the Board of Supervisors directing staff to prepare a Resolution of Intention (ROI) to contract the Community Regions & return to the Board with funding options.

Existing CR boundaries



Proposed



GREEN VALLEY ALLIANCE

SHINGLE SPRINGS COMMUNITY ALLIANCE

KEEPING SHINGLE SPRINGS RURAL

Community Regions

Public Comment -BOS-2/24/15

However ... a new ROI is redundant - Reason 1:

Amending the Community Regions is already included in the not-yet-completed General Plan update. From the Purvines Staff memo to the BOS, 9/23/2013:

2. *Comment:* The first 5-year General Plan review in April 2011 did not look at or subsequently dropped Community Regional Line Amendments from the Targeted General Plan Amendment (TGPA) process.

   Response: CRBs were reviewed in the first 5-year General Plan review, and are currently included in the TGPA. A fundamental component of the TGPA's environmental review was to provide a "Range of Options" to ensure the Board has flexibility to select the best option to meet the objectives of the project. Following the completion of the Targeted General Plan Amendment-Zoning Ordinance Update (TGPA-ZOU) environmental review, the Board may consider amendments to the CRBs.

Community Regions
Public Comment -BOS-2/24/15

GREEN VALLEY ALLIANCE

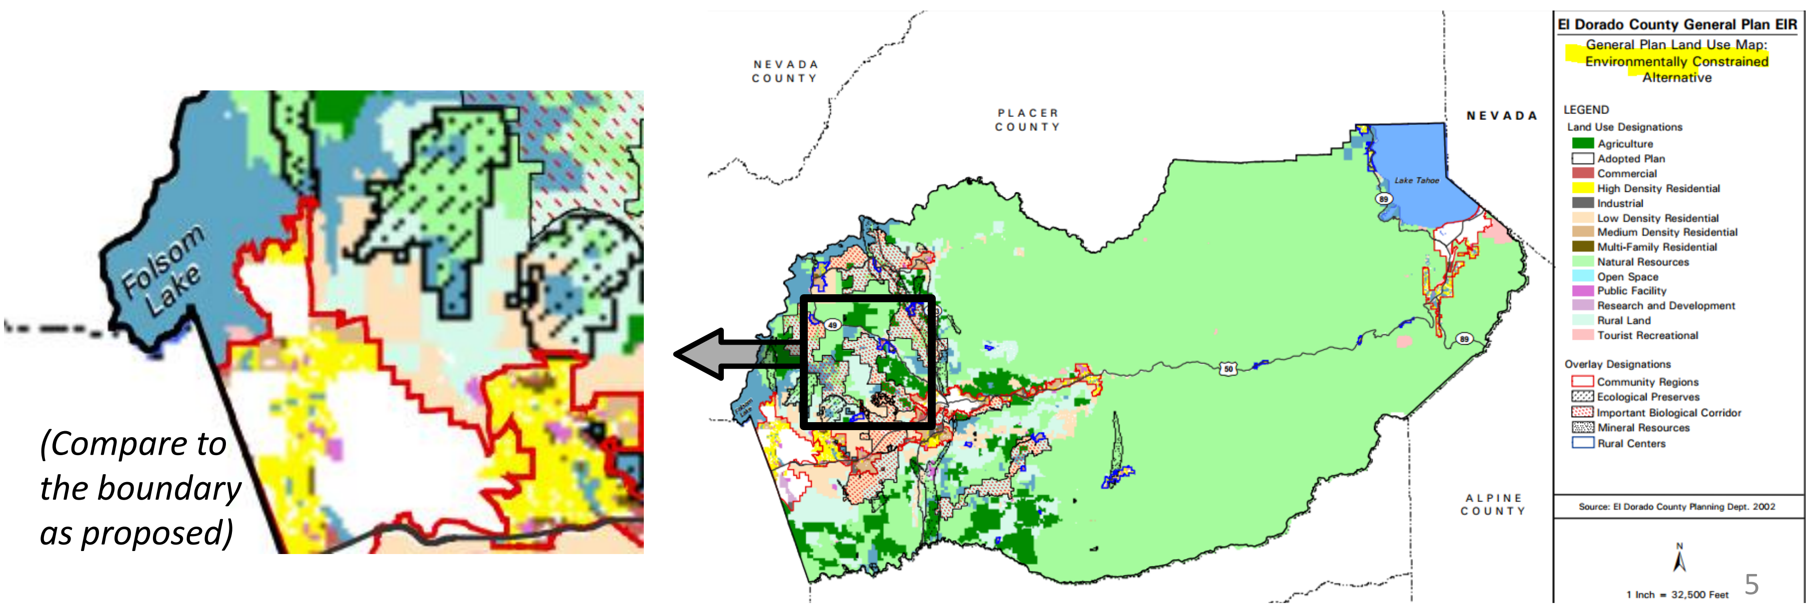
SHINGLE SPRINGS COMMUNITY ALLIANCE

KEEPING SHINGLE SPRINGS RURAL

A new ROI is redundant - Reason 2 :

The 'reduced' CRB's proposed were *already* analyzed in the 2004 General Plan EIR, so ***the Board is free to act on amending the boundaries***.

" The reduced size of Community Regions and Rural Centers would balance with the increased density of permitted subdivision to fully implement the intent of the General Plan to focus development in urban areas and protect rural areas from high levels of development " (excerpt from pg 5.1-45 of the 2004 General Plan EIR, Alternative #3, impacts discussion)



(Compare to the boundary as proposed)

GREEN VALLEY ALLIANCE

SHINGLE SPRINGS COMMUNITY ALLIANCE

KEEPING SHINGLE SPRINGS RURAL

Community Regions
Public Comment - BOS-2/24/15

A New Resolution today vs. reprioritizing the '2011' Resolution

• The inclusion of Community Regions in the EIR for the General Plan update means the boundaries can be amended (slide 4), *but the Board must direct staff to complete the process of analysis with the release of the Final EIR.* <u>*No new resolution is necessary, and NO additional EIR is necessary*</u>.

○ Because Rural Communities United challenged the draft EIR on this analysis, not directing it to be completed in the Final EIR would leave the County vulnerable to litigation on the Gen Plan update.

• The Major CIP update should be based on an accurate model of growth. The extent of the Community Region has significant influence on growth projections, and <u>*CRB review should have top priority rather than the least priority currently indicated*</u>.

• A new resolution is an option, but it must be on a parallel path or the General Plan update will be completed first and expose the county to legal action on analysis that should have been done and was not. <u>*A new resolution on a parallel path is redundant.*</u>

• Why delay when <u>*incorporating the Community Region boundary review in this update (the TGPA) will save time & money*</u>, and will assist in accurate growth projections for the CIP update, *particularly* when review is inevitable? Community groups do not understand the resistance.

Timeline follows.

GREEN VALLEY ALLIANCE

SHINGLE SPRINGS COMMUNITY ALLIANCE

KEEPING SHINGLE SPRINGS RURAL

Community Regions

291112 - Part 2

Public Comment - BOS-2/24/15

Timeline

April 2011 – BOS hearing. Staff recommends including Community Region review in the next General Plan update.

Nov 2011 – ROI's are adopted by the Board for the General Plan update, which include Community Region Boundary (CRB) review. [*From adopted ROI 182-2011: **Policy 2.1.1.1 and 2.1.2.1** Consider analyzing the possibility of adding new, amending or deleting existing Community Regions or Rural Center planning areas.]*

July 6, 2012 –Notice of Preparation (NOP) released for the General Plan update EIR, based on those adopted ROI's

December 18, 2012 - NOP's for Dixon Ranch and San Stino Environmental Impact Reports (EIR) are released, and County Staff denies the inclusion of CRB's in the current General Plan update (TGPA).

January - September 2013 – Residents pushed back trying to show CRB's must be included in the EIR for the TGPA.

September 30, 2013 – Staff agrees the CRB's are indeed supposed to be included, but requests to exclude them.

February 2014 – Staff again requests to put the CRB's outside the EIR update, and the Board agrees it would cause delay of the TGPA. Citizen groups hit the street with ballot initiatives.

December 2014 – After the November initiatives fail under the load of developer dollars, BOS votes for a new ROI.

February 24, 2015 – Today the proposed new ROI comes before the BOS, and the redundancy is apparent:

The 2011 ROI is already included in the Environmental Impact Report for the currently ongoing update of the General Plan (the TGPA), which is not yet complete.

Community Regions

Public Comment - BOS-2/24/15

GREEN VALLEY ALLIANCE

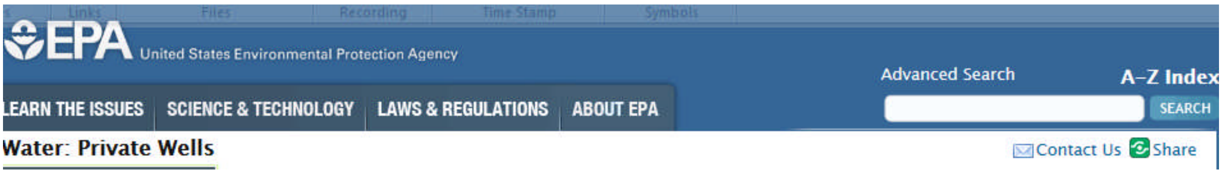
SHINGLE SPRINGS COMMUNITY ALLIANCE

KEEPING SHINGLE SPRINGS RURAL

Suggested Options to proceed:

1. Withdraw the request to adopt a *new* Resolution, and contract the Community Regions as proposed during the *current* General Plan update.
2. Utilize the analysis of the 'reduced' Community Regions from the adopted 2004 General Plan EIR, and contract the boundaries *now*, without delay.
3. Acknowledge that a new EIR is not necessary, and support citizen groups who have been working within the Planning process.

Do NOT defer yet again - return the subject parcels to the Rural Region



The first step to protect your health and the health of your family is learning about what may pollute your source of drinking water. Potential contamination may occur naturally, or as a result of human activity.

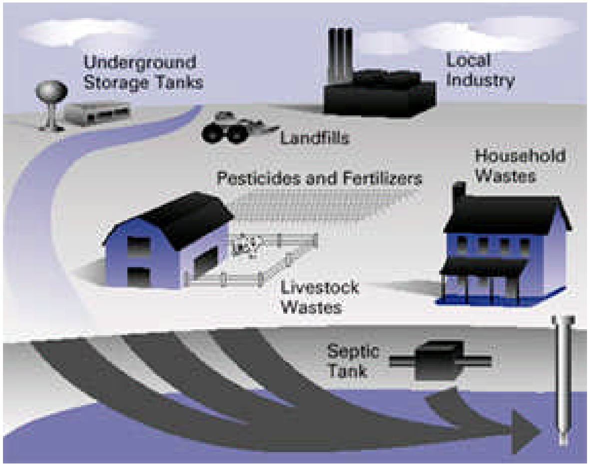
What are Some Naturally Occurring Sources of Pollution?

- **Microorganisms**: Bacteria, viruses, parasites and other microorganisms are sometimes found in water. Shallow wells — those with water close to ground level — are at most risk. Runoff, or water flowing over the land surface, may pick up these pollutants from wildlife and soils. This is often the case after flooding. Some of these organisms can cause a variety of illnesses. Symptoms include nausea and diarrhea. These can occur shortly after drinking contaminated water. The effects could be short-term yet severe (similar to food poisoning) or might recur frequently or develop slowly over a long time.
- **Radionuclides**: Radionuclides are radioactive elements such as uranium and radium. They may be present in underlying rock and ground water
- **Radon**: Radon isa gas that is a natural product of the breakdown of uranium in the soil — can also pose a threat. Radon is most dangerous when inhaled and contributes to lung cancer. Although soil is the primary source, using household water containing Radon contributes to elevated indoor Radon levels. Radon is less dangerous when consumed in water, but remains a risk to health.
- **Nitrates and Nitrites**: Although high nitrate levels are usually due to human activities (see below), they may be found naturally in ground water. They come from the breakdown of nitrogen compounds in the soil. Flowing ground water picks them up from the soil. Drinking large amounts of nitrates and nitrites is particularly threatening to infants (for example, when mixed in formula).
- **Heavy Metals**: Underground rocks and soils may contain arsenic, cadmium, chromium, lead, and selenium. However, these contaminants are not often found in household wells at dangerous levels from natural sources.
- **Fluoride**: Fluoride is helpful in dental health, so many water systems add small amounts to drinking water. However, excessive consumption of naturally occurring fluoride can damage bone tissue. High levels of fluoride occur naturally in some areas. It may discolor teeth, but this is not a health risk.

What Human Activities Can Pollute Ground Water?

-

- **Bacteria and Nitrates**: These pollutants are found in human and animal wastes. Septic tanks can cause bacterial and nitrate pollution. So can large numbers of farm animals. Both septic systems and animal manures must be carefully managed to prevent pollution. Sanitary landfills and garbage dumps are also sources. Children and some adults are at extra risk when exposed to water-born bacteria. These include the elderly and people whose immune systems are weak due to AIDS or treatments for cancer. Fertilizers can add to nitrate problems. Nitrates cause a health threat in very young infants called “blue baby” syndrome. This condition disrupts oxygen flow in the blood.



Septic tanks are designed to have a “leach field” around them — an area where wastewater flows out of the tank. This wastewater can also move into the ground water.

- **Concentrated Animal Feeding Operations (CAFOs)**: The number of CAFOs, often called “factory farms,” is growing. On these farms thousands of animals are raised in a small space. The large amounts of animal wastes/manures from these farms can threaten water supplies. Strict and careful manure management is needed to prevent pathogen and nutrient problems. Salts from high levels of manures can also pollute ground water.
- **Heavy Metals**: Activities such as mining and construction can release large amounts of heavy metals into nearby ground water sources. Some older fruit orchards may contain high levels of arsenic, once used as a pesticide. At high levels, these metals pose a health risk.
- **Fertilizers and Pesticides**: Farmers use fertilizers and pesticides to promote growth and reduce insect damage. These products are also used on golf courses and suburban lawns and gardens. The chemicals in these products may end up in ground water. Such pollution depends on the types and amounts of chemicals used and how they are applied. Local environmental conditions (soil types, seasonal snow and rainfall) also affect this pollution. Many fertilizers contain forms of nitrogen that can break down into harmful nitrates. This could add to other sources of nitrates mentioned above. Some underground agricultural drainage systems collect fertilizers and pesticides. This polluted water can pose problems to ground water and local streams and rivers. In addition, chemicals used to treat buildings and homes for termites or other pests may also pose a threat. Again, the possibility of problems depends on the amount and kind of chemicals. The types of soil and the amount of water moving through the soil also play a role.
- **Industrial Products and Wastes**: Many harmful chemicals are used widely in local business and industry. These can become drinking water pollutants if not well managed. The most common sources of such problems are:

   - **Local Businesses**: These include nearby factories, industrial plants, and even small businesses such as gas stations and dry cleaners. All handle a variety of hazardous chemicals that need careful management. Spills and improper disposal of these chemicals or of industrial wastes can threaten ground water supplies.
   - **Leaking Underground Tanks & Piping**: Petroleum products, chemicals, and wastes stored in underground storage tanks and pipes may end up in the ground water. Tanks and piping leak if they are constructed or installed improperly. Steel tanks and piping corrode with age. Tanks are often found on farms. The possibility of leaking tanks is great on old, abandoned farm sites. Farm tanks are exempt from the EPA rules for petroleum and chemical tanks.
   - **Landfills and Waste Dumps**: Modern landfills are designed to contain any leaking liquids. But floods can carry them over the barriers. Older dumpsites may have a wide variety of pollutants that can seep into ground water.
- **Household Wastes**: Improper disposal of many common products can pollute ground water. These include cleaning solvents, used motor oil, paints, and paint thinners. Even soaps and detergents can harm drinking water. These are often a problem from faulty septic tanks and septic leaching fields.
- **Lead & Copper**: Household plumbing materials are the most common source of lead and copper in home drinking water. Corrosive water may cause metals in pipes or soldered joints to leach into your tap water. Your water's acidity or alkalinity (often measured as pH) greatly affects corrosion. Temperature and mineral content also affect how corrosive it is. They are often used in pipes, solder, or plumbing fixtures. Lead can cause serious damage to the brain, kidneys, nervous system, and red blood cells. The age of plumbing materials — in particular, copper pipes soldered with lead — is also important. Even in relatively low amounts these metals can be harmful. EPA rules under the Safe Drinking Water Act limit lead in drinking water to 15 parts per billion. Since 1988 the Act only allows "lead free" pipe, solder, and flux in drinking water systems. The law covers both new installations and repairs of plumbing.
   - For more information on avoiding lead in drinking water, visit the EPA's Lead in Drinking Water web site.
- **Water Treatment Chemicals**: Improper handling or storage of water-well treatment chemicals (disinfectants, corrosion inhibitors, etc.) close to your well can cause problems.

Chapter 1
Introduction

Riparian areas provide important ecological functions (Table 1-1). They occupy the land between stream channel banks and adjacent uplands, and generally correspond to stream floodplains. These areas are transitional between terrestrial and aquatic ecosystems, and they contain gradients in hydrology, soils, ecological processes and biota (Brinson et al. 2002). Consequently, they perform ecological functions that are distinct from other components of the landscape. For example, riparian areas convey floodwaters and are important sites of denitrification, which returns nitrogen to the atmosphere. In western Placer County, they also provide essential habitat areas for a high diversity of aquatic and terrestrial wildlife species (Zeiner et al. 1988, 1990a,b; Moyle et al. 1996), including numerous threatened, endangered, and other special-status species that have been proposed for coverage under the Placer County Natural Community Conservation Plan (NCCP) and Habitat Conservation Plan (HCP) for the Phase I Planning Area (Jones & Stokes 2004a).

Because these areas provide such important ecological functions (including fish and wildlife habitat), a number of measures have been proposed to conserve riparian areas and aquatic ecosystems; these measures include establishing zones with land use restrictions (i.e., setbacks) around streams and riparian areas. Setbacks from streams and riparian areas have been widely recognized as necessary conservation measures. For example, the *Placer Legacy Open Space and Agricultural Conservation Program Implementation Report* (Placer County Planning Department 2000), which provided direction for development of a Placer County NCCP/HCP, identified Riparian and Stream Protection Zones (RSPZs) as an important component of the NCCP/HCP. Non-development setbacks encompassing and adjacent to riparian zones and streams are routinely recommended by local, state, and federal agencies including the Placer County Planning Department, the California Department of Fish and Game (DFG), the U.S. Fish and Wildlife Service (USFWS), and the National Oceanic and Atmospheric Administration National Marine Fisheries Service (NOAA Fisheries). These agencies have identified a need in western Placer County (and elsewhere in the Sacramento Valley) to develop a strong scientific foundation for recommending stream and riparian setbacks that include buffers to reduce effects from adjacent land uses.

The current study was designed to support efforts by the Placer County Planning Department to develop this scientific foundation for the establishment of stream and riparian setbacks. Its purpose was to review existing literature and make specific recommendations for riparian setbacks—particularly the width of such setbacks—that can be used in the California Environmental Quality Act (CEQA) or NCCP/HCP processes.

This report summarizes the results of the review. Each chapter addresses a set of related ecological functions performed by riparian areas and streams, as listed below.

- Hydrologic and geomorphic functions (e.g., groundwater recharge, sediment transport).
- Biogeochemical functions (e.g., nutrient cycling, degradation of contaminants).
- Provision of salmonid habitat.
- Provision of riparian plant habitat.
- Provision of wildlife habitat.

Each chapter describes the pertinent functions mechanistically, reviews the effects of human alterations on the functions, assesses the relationships between setback width and human activities, and concludes with recommendations for setback widths. The recommendations are intended to provide for long-term conservation of the relevant function by protecting the riparian area as well as a defined buffer that will reduce the effects of adjacent land uses on riparian and aquatic systems. In these recommendations, and throughout the report, all distances refer to only one side of streams.

The report concludes with an overall setback recommendation that includes setback widths and guidance regarding uses of setback land that may be compatible with resource conservation.

Table 1-1. Ecological Functions of Riparian Ecosystems[a]

Hydrologic and Geomorphic Functions
Recharge of groundwater
Storage of surface water
Conveyance of floodwaters and other overland flows
Transport of sediment
Storage of sediment
Biogeochemical Functions
Production of biomass (i.e., primary production)
Storage of carbon in vegetation and soil
Cycling of phosphorus
Cycling of nitrogen
Cycling of micronutrients
Adsorbtion, storage, and transformation of non-nutrient metals (e.g., mercury)
Adsorbtion, storage, and degradation of pesticides and hydrocarbons
Habitat Functions
Sustenance of characteristic plant associations
Sustenance of aquatic animal habitats
Sustenance of terrestrial animal habitats

[a] Based on lists of functions in Keddy 2000 and Brinson et al. 2002.

Chapter 2
Hydrologic and Geomorphic Functions

Overview

Hydrologic and geomorphic functions involve the transport and storage of water and sediment. Streams—comprising stream channels and floodplains—are integral to the provision of those functions. Riparian vegetation occupies floodplains; for the purposes of this report, riparian areas may be considered synonymous with floodplains. Sediment and water are transported to streams from throughout the watershed; upon reaching the stream, sediment and water move down the stream and occasionally outwards onto the floodplain. In response to these inputs of water and sediment, the form of stream channels and floodplains changes. These dynamic changes can in turn affect most ecological functions provided by riparian areas and aquatic ecosystems. This chapter describes these processes and the effects on them caused by human activities. The chapter concludes with an assessment of the relationship of setback width and human effects, and offers the project team's recommendation for setback widths to conserve hydrologic and geomorphic functions.

Effects of Human Alterations on Movement of Water and Sediment to Riparian Areas and Streams

Watershed Hydrology

In the absence of human alterations (e.g., interbasin water transfers), streamflows originate from the precipitation falling throughout a stream's watershed. Rainfall is the predominant form of precipitation in most of western Placer County. Before reaching a stream, precipitation may infiltrate to become groundwater or return to the atmosphere through evapotranspiration. Human alterations affect the proportion of precipitation following each of these pathways, and thus the quantity and timing of streamflows, which in turn influences geomorphic functions in the stream corridor.

Evapotranspiration

Evapotranspiration is the loss of water to the atmosphere due to the diffusion of water vapor from the interior of plant leaves (transpiration) and from soil and other surfaces (evaporation). It can dominate a watershed's water balance and can influence soil moisture content, groundwater recharge, and streamflow.

Air temperature and humidity determine the potential rate of evapotranspiration, whereas water availability determines its actual rate. Under cool or moist conditions, water availability does not limit evapotranspiration; actual and potential evapotranspiration are equal. Under drier and warmer conditions, as surfaces and soils dry, plants reduce their use of water by a combination of closing their leaf pores (i.e., stomata), changing leaf angles, losing leaves, becoming dormant, or dying (Barbour et al. 1998). Thus, under dry and warm conditions, actual evapotranspiration is limited by water availability.

Not all water is available for evapotranspiration. Only water stored at the earth's surface (i.e., surface water and water intercepted by surfaces) or in soils is available for evapotranspiration. Therefore, the timing of precipitation and the time water resides in a watershed strongly influence actual evapotranspiration.

Western Placer County has a Mediterranean-type climate, characterized by concentration of rainfall during the coldest months of the year. Consequently, only water stored in soils, streams, and other water bodies is available for evapotranspiration during summer months when the potential evapotranspiration is greatest. During these months, vegetation can remove a substantial fraction of the water within riparian areas and streams. For example, in July in the Sacramento Valley, potential evapotranspiration is about 0.8 centimeters (cm) (0.3 inches [in]) per unit area each day (California Department of Water Resources 2004). This corresponds to about 18 acre-feet of water being transpired by 1.6 kilometers (km) (1 mile [mi]) of a riparian corridor 30 meters (m) (98 feet [ft]) wide on each side of a stream.

Human alterations can increase or reduce evapotranspiration. Importing water from other watersheds or withdrawing groundwater from below the rooting zone to irrigate agricultural lands and landscaping can increase evapotranspiration by increasing the availability of water. Removing vegetation or increasing runoff can reduce evapotranspiration. Alterations that remove vegetation include both the temporary removal of biomass (e.g., timber harvesting, woodcutting) and the permanent conversion of natural vegetation to developed land uses with impervious surfaces (e.g., roofs, paved roads). Alterations affecting runoff are described in the next section.

Runoff

There are three basic types of runoff.

- Overland flow.
- Subsurface flow.
- Saturated overland flow.

Each of these runoff types can occur individually or in some combination in the same locale. Despite involving belowground flow, subsurface and saturated overland flow are considered components of runoff because they are closely linked to overland flow.

Overland flow occurs when the rate of rainfall or snowmelt exceeds the rate of water movement into the soil (i.e., infiltration rate). The infiltration rate is affected by soil structure and moisture content (infiltration diminishes as water saturates a soil). Areas with natural vegetative cover and leaf litter usually have high infiltration rates. These features protect the surface soil pore spaces from being plugged by fine soil particles as a consequence of raindrop splash.

Overland flows may subsequently enter the soil as rainfall diminishes in intensity or ceases, or they may reach a stream channel before entering the soil. Slope and vegetation affect the speed of overland flow, and thus the portion that discharges directly into stream channels.

Subsurface flow is a storm-generated pulse of groundwater. Once in the soil, water moves in response to differences in hydraulic head (i.e., the potential for flow resulting from a difference in hydrostatic pressure at different elevations). Before a storm, where the water table slopes toward a stream, water moves down and into the stream channel as baseflow. During a storm, as rainwater infiltrates the soil, the water table can rise more rapidly near the stream than it does further upslope. This can happen when the soil near the stream has greater moisture content and a shorter distance to the water table than does soil upslope. As the water table becomes locally steeper, this newly arrived groundwater moves relatively rapidly towards the stream channel, mixes with baseflow, and increases groundwater discharge to the channel.

Saturated overland flow is a combination of direct precipitation and subsurface flows. Where the water table reaches or emerges from the surface, soils are saturated. Consequently, all rain falling on these soils, as well as emerging groundwater, flows downslope as overland runoff.

Human alterations increase runoff by reducing the soil's infiltration capacity (i.e., maximum rate of infiltration). Conversion of natural vegetation to developed land cover causes the greatest reduction in infiltration. However, agricultural lands also exhibit reduced infiltration capacity compared to natural vegetation. Heavy machinery, livestock, and even humans can compact soils, reducing infiltration. Moreover, removal of vegetation can expose the soil surface to the impacts of raindrops, reducing soil pore spaces and infiltration. In western Placer County, these alterations have affected extensive portions of the landscape. For example, along the major streams of western Placer County, approximately a quarter of the land < 20 m (66 ft) from the centerline of a stream, is in developed or agricultural land-cover (Jones & Stokes 2004a, 2004b).

Groundwater

Gravity causes water to move downward through soil until it reaches an area already saturated with water. The top of this saturated zone defines the groundwater table. However, the movement of groundwater may be quite complex. The permeability of sediments and rock strongly influences the rate of groundwater movement. Water moves easily through larger pores and more slowly through smaller pores. In addition, layers of sediment or rock with low permeability (i.e., confining beds) may severely restrict groundwater movement. Thus, where the permeability of sediments and rock varies considerably, complex patterns of groundwater movement may occur. Riparian areas typically have considerable variability in the permeability of their sediments.

Human alterations can affect groundwater through several different mechanisms. First, activities that affect runoff or evapotranspiration affect the proportion of precipitation that becomes groundwater. Second, because streamflows can be an important source of groundwater, alterations that reduce streamflows can also reduce inputs to groundwater. Third, alterations that affect the quantity of groundwater (i.e., groundwater withdrawals) can change the elevation of the groundwater table. Drainage ditches and tiles also lower the water table's elevation.

Erosion

Gravity, wind, and water transport soil to riparian areas and streams. Soil is dislodged when the force of wind, water, or gravity exceeds the forces holding soil in place. Several factors affect the balance of these forces: the soil's physical properties; vegetation structure; topography; and the quantity, concentration, and speed of runoff. Soil characteristics, such as lithology (i.e., rock or mineral content), cohesion, and granulometry (i.e., grain size association), influence the erodibility of soils. Vegetation reduces erosion by binding soil particles and by slowing wind and water (Brinson et al. 2002); accordingly, greater cover of vegetation reduces the potential for erosion. Because both velocity and shear stress increase with slope, the potential for erosion increases with the angle and length of upland slopes. Also, as more runoff is generated and concentrated (i.e., greater runoff depth), the force exerted by flowing water on the soil surface—and hence erosion— increases.

Gravity can also induce the slow downhill movement of soil and rock (i.e., soil creep) and mass failures such as debris flows. In steep terrain, mass failures can transport enormous quantities of sediment into riparian areas and stream channels. Mass failures are often triggered by intense rainstorms falling on saturated soils (Swanston 1991). Under such conditions, soil is particularly heavy due to the added water, and subsurface flows can reduce the forces that offset gravity. Although western Placer County generally has gently sloping topography, that is not conducive to mass failures, slopes can be steep along stream channels, particularly near the area's eastern boundary in the Sierran foothills.

The magnitude and distribution of erosion in watersheds affect the yield of sediment to the stream corridor. Soil erosion can occur gradually over a long period or it can be cyclic or episodic, accelerating during certain seasons or during certain rainstorm events (Grove and Rackham 2001). Erosion does not proceed at a uniform rate, because rainstorms are episodic events of varied intensity and because the forces binding soils continually change with temperature, moisture content, and vegetation structure.

Human activities strongly alter patterns of erosion and thus the quantity of sediment entering riparian areas and streams. In the Sacramento Valley and adjacent foothills, human-induced fine sediment loading is primarily due to changes in land use that both alter the vegetative cover and increase runoff. The three main land uses generating sediment in the region are agriculture, in-channel mining, and construction activities. The effects of silvicultural activities, though discussed in this section, are concentrated at higher elevations in the central and eastern portions of the county.

Agriculture generally exposes friable topsoils to raindrop erosion, which has the potential to generate large amounts of sediment (Waters 1995). In the Sacramento Valley and adjacent foothills, additional land is still being converted from natural vegetation to agriculture. Much of this new agricultural land is of marginal quality and on relatively steep slopes, and is consequently likely to generate more sediment than agricultural land with gentler slopes (Charbonneau and Kondolf 1993).

Gravel mining can increase fine sediments in streams and streambeds. Gravel mines are often in the active floodplain or even the stream channel itself, and because processing of aggregate occurs on site, this activity can add fine sediment directly to the stream and streambed. Gravel mining is on-going in the historic floodplains of at least two streams in western Placer County (EDAW 2004; Jones & Stokes 1999).

Forestry practices, including clear-cutting, skidding, yarding, site preparation, and road construction and maintenance, can substantially increase sediment input to streams. Poorly designed logging roads and skid trails are persistent sources of sediment. Open slopes with soils exposed by yarding activities, scarification, or by associated mass failures or fires erode easily (Chamberlain et al. 1991).

Residential development, industrial construction, streets and utilities, and other urban infrastructure elements can increase sediment movement to streams

(Waters 1995). Excavation for infrastructure construction and maintenance is a primary source of sediment transported to streams. Development on steep hillsides further increases erosion and transport of sediment (Renard et al. 1997).

In addition to these effects of general types of land use activities, roads, graded and recontoured land, and the routing of stormwater drainage can all spatially concentrate runoff, and hence increase both surficial erosion and the likelihood of mass failures.

Effects of Human Alterations on Water and Sediment Movement along Streams

Flow Regime

Streamflows originate in runoff and groundwater entering the stream channel. As this water moves along the stream it may follow several different pathways. Some water will evaporate from the surface of the flow. Some will enter the sediments underlying the channel and floodplain, where it will intermix with groundwater in a zone (i.e., the hyporheic zone) that can extend from several to more than a hundred meters from the channel (Brunke and Gonser 1997). (This hyporheic zone is habitat for invertebrates and microbes that have important roles in nutrient cycling and the degradation of pollutants.) Stream water entering the hyporheic zone may reenter the channel downstream; alternatively, in reaches where the water table is lower than the stream channel, the water entering the hyporheic zone may continue to flow away from the stream toward the water table. During high streamflows, the channel may not be able to convey the entire flow, and streamflows spill over the channel banks onto the floodplain, and may or may not reenter the channel downstream.

Streamflows are typically highly variable across days, seasons, and years. Most aspects of a stream's flow regime (i.e., the pattern of streamflow), including magnitude, frequency, timing, and duration, have consequences for sediment transport and channel form, and indirectly or directly affect organisms. For example, low flows can reduce the area of aquatic habitats. High flows can wash away eggs or, through sediment movement, can sustain or degrade habitats. Rapid declines in flow can strand fish.

Together with the pattern of water inputs from the watershed, channel form and vegetative structure determine a stream's flow regime. The slope, area, form, and roughness (i.e., irregularity of the surface) of the channel and floodplain surface determine the depth and velocity of streamflows, as well as their magnitude and duration.

As a stream's discharge (i.e., the volume of water discharged per unit time) increases, either flow velocity, flow area, or both must increase. Similarly, as water flows along a stream, the depth, velocity, and cross-sectional area of the flow change to maintain a constant discharge. This occurs because as more water enters than exits a section of channel, the volume of water in that section increases, changing the width and depth of the flowing water until the discharge entering the segment equals the exiting discharge. As width and depth change flow velocity changes.

Flow velocity is a product of slope (which causes water to accelerate as it moves downhill) and the surface over which the water flows (the character of which can impede or facilitate the water's passage through friction or the lack of it). At a given slope, water velocity decreases as the roughness of the inundated surface increases. Vegetation, coarse sediment, and larger obstacles all increase roughness. For example, the encroachment of woody plants into a stream channel reduces the velocity of water, and consequently the channel's capacity to convey floodwaters before inundating the floodplain; for this reason, woody plants are removed from many stream banks to maintain floodwater conveyance.

Flow regime is changed to some degree by all human activities that alter the quantity or timing of water inputs to streams or the movement of flows along streams. Surface water diversions, groundwater withdrawals, and inter-basin water transfers change the quantity of water entering streams. When these waters are used for irrigation during California's summer dry season (and subsequently drain back to streams), they change the seasonality as well as the levels of flows. Conversions of land cover throughout the watershed affect the rate at which water enters streams. As described in *Watershed Hydrology* above, replacement of natural vegetation with agricultural or developed lands increases runoff. This increased runoff results in higher peak streamflows because, after rainstorms, runoff enters streams much more rapidly than does groundwater. Decreased infiltration is also associated with increased runoff; such decreased inputs to groundwater can reduce low flows, and can even convert a perennial flow regime to a seasonal or intermittent one. These changes are most dramatic along urban streams where much of the watershed consists of developed lands with a high proportion of impervious surfaces (Hollis 1975; Macrae 1996; Booth and Jackson 1997; Paul and Meyer 2001).

Interbasin water transfers are a particularly significant human alteration of flow regimes in western Placer County (Jones & Stokes 2004b). Water is diverted from the Bear River's watershed into Coon Creek, Doty Ravine and Auburn Ravine. Water is also diverted from the American River's watershed into Auburn Ravine. Because large quantities of water (about 20,000 acre-feet) are transferred by the Placer County Water Authority (PCWA) from the American River watershed to the City of Roseville, it is likely that interbasin transfers augment flows in the Dry Creek watershed as well (ECORP 2003).

Modifications of channels and floodplains also alter flow regime. Vegetation removal that is conducted to clear channels or that results from grazing, logging, or conversion to agricultural and developed lands can reduce roughness, thereby increasing flow velocities. Physical alterations to the channel and floodplain (e.g., channelization, levees, berms) also changes flow regimes. For example, the straightening and deepening of the channel to improve conveyance (channelization) speeds velocities and increases peak flows downstream. Dams and reservoirs can affect all aspects of flow regimes, and in some instances replace the previous flow regime with a new regime determined by the schedule of releases from a reservoir. Common downstream effects of reservoirs include a reduction in overall flows, reduced peak flows, and rapid changes in discharge (Stanford et al. 1996; Brinson et al. 2002). Along some Sacramento Valley streams, reservoir releases in conjunction with drainage from irrigated lands have increased summer flows, converting seasonal flow regimes to perennial ones.

Sediment Transport

Sediment transport is directly related to stream power. A stream's power is a product of its discharge, the specific weight of water (which is essentially a constant), and slope. Stream power represents the quantity of work that a streamflow can perform (i.e., the rate of potential energy expenditure per unit length). Most of this energy is dissipated overcoming friction at the channel and floodplain surface, but a small portion moves sediment.

The portion of stream power that moves sediment depends on several stream attributes. The movement of sediment downstream only occurs when the force exerted by water along the surface of the channel (shear stress) exceeds the forces holding sediment in place. The magnitude of shear stress and the forces that offset it are affected by the following factors.

- Flow depth and velocity.
- Channel morphology.
- Sediment size.
- Adhesion of particles.
- Binding of particles by roots.

Sediment transport is increased by conditions that concentrate the force of flowing water (e.g., confining flow to a narrower channel) or reduce the resistance of particles to their displacement (e.g., loss of vegetation and hence of roots).

Sediment transport in any given stream is greatest during peak flows. Not only does shear stress increase with flow depth and velocity, but the relationship between shear stress and sediment transport is non-linear (Gordon et al. 1992). In other words, the increased force exerted by peak flows results in a disproportionate increase in the capacity to transport sediment.

Human alterations affect sediment transport by changing flow regime or sediment inputs to streams, and by blocking the continuity of sediment delivery along a stream. Human effects on flow regime and sediment inputs have already been described in the flow regime and erosion sections of this chapter. The movement of sediment along a stream may be blocked by dams or reduced by pits from gravel mining. Dams block the downstream movement of coarser sediment from the upper portions of watersheds of most rivers and streams in the Sacramento Valley. In-stream gravel mining produces pits that trap incoming sediment (Mount 1995).

Effects of Human Alterations on Channel and Floodplain Form

The form of stream channels and their floodplains affects the important stream and riparian functions listed below.

- Transport and storage of sediment.
- Conveyance of floodwaters.
- Provision of floodplain habitats.
- Provision of aquatic habitats.

For example, the shape and gradient of channels affects the location of areas of sediment deposition and removal. Similarly, fish spawning and rearing habitats are affected by the interplay of channel geometry with flow depth, velocity, and the scour and deposition of sediments.

The form of a stream’s channel and floodplain is a product of water and sediment inputs from the watershed, geologic constraints, channel or floodplain vegetation, and historic events. Consequently, changes in sediment inputs, flow regime, or vegetation cause changes in channel and floodplain form. These geomorphic responses can be complex because of interactions among these important factors. Flow regime, sediment transport, and vegetation influence each other; changes in channel and floodplain form likewise affect the growth of plants and the movement of water and sediment. Consequently, changes in a watershed may cause channels and floodplains to undergo complex patterns of change across decades.

Channel Morphology

In the absence of human alterations, the form of stream channels is not static, unless constrained by geology. Channel and floodplain morphology changes slowly in response to long-term changes in climate; it can also change rapidly in response to periodic intense storms or to massive inputs of sediments from slope failures.

Human alterations often cause changes in flow regime and sediment input that lead to unstable channels with rapidly changing forms. Unstable channels result from rates of erosion and sedimentation that are much more rapid than in comparable, but relatively unaltered, streams (Doyle et al. 2000). This instability can affect riparian and stream biogeochemical and habitat functions (Paul and Meyer 2001; Brinson et al. 2002).

Channel instability has both horizontal (channel bed) and vertical (channel banks) components. A longitudinal section of streambed is stable when the size and quantity of sediment entering the section equals the size and quantity of sediment carried downstream. If the capacity of flows to transport sediment changes (e.g., change in peak flows) without a corresponding change in sediment inputs, or vice versa, then net erosion or deposition will occur and the channel may become unstable. The rising (i.e., aggradation) or lowering (i.e., incision or degradation) of channel beds generally alters flows of groundwater and surface water through riparian areas by changing the elevation or slope of the water table, and by changing the discharge necessary for overbank flows.

The stability of channel banks is affected not only by the shear stress of flowing water, but also by the force of gravity pulling bank sediments downward, which can lead to mass failure of sections of bank (i.e., bank failure). The binding of sediment particles by plant roots can substantially reduce bank erosion. A tree's roots typically extend up to twice the radial distance of the tree's crown; thus, in western Placer County, trees up to 20 m [66 ft] from the channel may contribute to bank stability. Therefore, bank retreat (i.e., net linear recession of the bank) is increased not only by changes in flow regime that increase shear stresses, but also by removal of vegetation along the banks (Lawler et al. 1997).

Human alterations affect channel stability through changes of flow regime, sediment transport, or channel vegetation, or by placing structures along or in the channel. Human activities altering flow regime, erosion, and sediment transport are described in the respective sections of this chapter. Their net affect on channel form is to alter the balance between erosion and deposition along the stream channel, causing a corresponding change in channel form.

Channel bank vegetation is directly altered by grazing, channel maintenance, wood cutting and timber harvesting, land-cover conversion, and even by the trampling associated with intensive recreational use. All these activities may lead to bank retreat. With the exception of timber harvesting, these activities occur locally along western Placer County's streams (Placer County 2002; Appendix A)

Channel vegetation is also altered by activities that change flow regime, water table elevation, or channel stability. If changes to flow regime or water table elevation reduce water availability during the growing season, vegetation will be altered and will probably exhibit reduced roughness or a lower density of roots to bind bank sediments. Conversely, reduced flows may allow riparian vegetation to establish on lower-elevation surfaces within the channel, where establishment and survival were previously not possible because of scouring or prolonged submergence (Pelzman 1973). The latter scenario has occurred along a number of Sacramento Valley streams below dams (Pelzman 1973; CALFED 2000b). This encroachment of vegetation on the channel stabilizes channel sediments.

The changes in erosion, runoff, and peak flows associated with conversion of natural vegetation to developed land cover generally cause channel instability (Paul and Meyer 2001). Though channels may transiently aggrade with sediment eroded from construction sites, the higher flow peak flows associated with runoff from developed lands are capable of eroding and transporting more sediment (Wolman 1964). This tends to cause channel incision, bank retreat, or both, and a resulting increase in the channel's cross-sectional area. The slope and meanders of stream channels also may change (Riley 1998). Other changes in vegetation or land cover may cause effects comparable to those from conversion to developed lands. Incision is widespread along western Placer County's streams, and has reduced the area of floodplain inundated by floodflows, and thus detrimentally affected most riparian functions (Placer County 2002; EDAW 2004; Jones & Stokes 2004c).

All structures constructed in the channel or active floodplain to some degree alter flows and sediment erosion and deposition, and thus have consequences for channel form. The most substantial effects result from bank protection, berms and levees, and dams. Bank protection (e.g., stone revetment, riprap) is installed for the purpose of reducing lateral movement of the channel. Berms and levees restrict floodwaters to a small portion of the floodplain, and thus may create deeper and faster peak flows capable of eroding and transporting more sediment, which in turn may expand channel cross-sectional area. Berms and bank protection exist occur along western Placer County's streams, particularly at lower elevations. Other structures include numerous road crossings and about thirty dams (County of Placer 2002; DWR 2002; Bailey Environmental 2003; Foothill Associates 2004; Jones & Stokes 2004b)

The construction of dams to form reservoirs contributes to accelerated channel erosion below the dams and to changes in the particle size on the riverbed (Kondolf 1997). Water released from dams is relatively free of sediment, particularly coarse sediment (i.e., larger than 2 mm in diameter). The relatively sediment-free flow results in net erosion of channel bed and banks, often leading to channel incision. Without the input of coarse sediment from upstream, the area of gravel beds in the channel is reduced, and the remaining gravel is often of larger sizes that are not mobilized by flows released from the dam (i.e., armoring of the channel). Dams also reduce peak flows, resulting in a reduction of channel size and accumulation of finer sediment along and within the river channel (Kondolf 1997). Flashboard dams, however, may have lesser effects if removed during peak flows. Most dams in western Placer County are flashboards dams, and many are removed during peak flows (DWR 2002; Placer County 2002; Bailey Environmental 2003)

Stream channel shape is directly altered by channelization and in-channel gravel mining. As mentioned earlier in this chapter, channelization converts streams into deeper, straighter, and often wider shapes to improve conveyance of floodwaters. It increases peak flows and can promote channel instability, which may lead to lowering of the water table (Gordon et al. 1992). In-channel gravel mining removes material from the channel bed and thus lowers its elevation (Bravard et al. 1997).

Floodplain Morphology

The active floodplain is the geomorphic surface adjacent to the stream channel that is typically inundated on a regular basis (i.e., a recurrence interval of about 2–10 years or less). It is the most extensive low depositional surface, typically covered with fine overbank deposits, although gravel bar deposits may occur along some streams. The floodplain surface often contains abandoned channels or secondary channels (i.e., chutes).

The stream migrates laterally across the floodplain as the outside of the meander bend erodes and the point bar builds with coarse-textured sediment. This naturally occurring process maintains the cross section needed to convey water and sediment from the watershed.

Floodplains are built by two stream processes: lateral and vertical accretion. Lateral accretion results from differential erosion and deposition along the channel. In unconstrained rivers, bank retreat is concentrated on the outside (concave side) of bends in the channel (i.e., meanders), forming cut banks; deposition occurs on the inside (convex side) of bends, forming point bars. This difference in erosion and deposition along channel bends causes channels to migrate across the floodplain. Other floodplain features also arise through channel migration. Where bends become cut off at their base (because erosion joins their upstream and downstream ends), oxbow lakes are formed. Where higher flows cross over point bars, chutes may form. Channel shifts to old or new courses (i.e., channel avulsion) can occur during floodflows, and may cut off meander bends and change the channel's form.

Vertical accretion is the deposition of sediment on flooded surfaces. It occurs when flows exceed the channel's conveyance capacity, inundate the floodplain, and deposit sediment. Though most floodplain sediment is deposited through lateral accretion (Leopold et al. 1964), overbank flows and the associated vertical accretion have a significant effect on aquatic and floodplain habitats that are described in subsequent chapters of this report.

Lateral and vertical accretion are affected by human alterations that modify flow regime, sediment supply, and channel stability or that construct structures within the floodplain. Human alterations affecting flow regime, sediment transport, and channel form alter the rate of channel movement and the frequency of overbank flows. These alterations, including the effects of dams, have been described in the preceding sections of this chapter. All structures within the channel or floodplain alter flows and accretion to some degree. However, the most substantial alterations are bank protection, which is installed specifically to reduce lateral channel migration, and berms and levees, which restrict floodwaters, and thus vertical accretion, to a small portion of the floodplain.

Relationships Between Human Effects and Riparian Setback Width

Riparian setbacks can reduce the effects of human alterations on water and sediment inputs to streams; if they extend beyond the active floodplain, setbacks can also reduce direct effects on flow regime, sediment transport, and channel and floodplain morphology. However, many effects of human alterations on hydrologic and geomorphic functions would be relatively unaltered by setbacks.

There has been considerable research on the effects of natural riparian vegetation or managed buffers on the movement of runoff and suspended sediment. (This literature has been reviewed by Castelle et al. 1992; Wenger 1999; Brinson et al. 2002; Lowrance et al. 2002; Correll 2003). This research indicates that setbacks have three beneficial effects: slightly reducing the area of sediment sources in a watershed, increasing the distance of runoff and erosion sources from streams, and interposing a zone of vegetation with high roughness and high infiltration capacity between streams and sources of runoff and erosion. The roughness of both natural and managed vegetation can slow runoff and cause the deposition of sediment before it reaches the stream. This deposition of sediment increases with vegetation width; at any given width, deposition is greatest when flows are evenly distributed (not locally concentrated) and when vegetation and topography are uniform (Herrone and Hairsine 1998; Wenger 1999; Brinson et al. 2002).

Numerous studies document the effectiveness of managed or natural vegetation in removing suspended sediment, particularly sands and silts, from runoff before it reaches stream channels (Castelle et al. 1992; Wenger 1999; Brinson et al. 2002; Lowrance et al. 2002). (Because clay particles are very small [less than 2 μm], they remain suspended even in still water for hours, and thus are much more likely to remain in runoff.) If this sediment is deposited on the active floodplain, it may be only temporarily stored there before entering the stream channel. However, if sediment is removed from runoff before it reaches the floodplain, it is much less likely to be remobilized into the stream channel. Setbacks may also reduce the likelihood of mass failures on adjacent slopes by including susceptible terrain inside the buffer, where human alterations are less likely to cause mass failures (Rhodes 1994; Tang and Montgomery 2004).

There is considerable variation among the results of studies assessing the relationship between the width of buffers and sediment removal from runoff. A number of studies document narrow buffers (less than 10 m [33 ft]) removing substantial amounts of sediment from runoff (Castelle et al. 1992; Wenger 1999; Lee et al. 2000; Hook 2003). However, many of these have been short-term studies or studies of managed buffers that were conducted under a narrow range of conditions. Short-term studies probably underestimate the distance sediment is able to be moved across buffers because erosion is a highly variable process, largely associated with intense storms and other unusual events (Grove and Rackham 2001). Similarly, small-scale studies of managed buffers probably underestimate the quantity of sediment that is able to cross unmanaged buffers because natural topography and vegetation are quite varied, and can concentrate flow, have less roughness than managed vegetation, or provide additional sources of runoff or sediment at some locations. These findings are supported by other studies that have indicated wider buffers (20–60 m [66–197 ft]) are necessary to remove most sediments (Cooper and Gilliam 1987; Castelle et al. 1992; Davies and Nelson 1994; Wenger 1999). These include longer-term studies that have shown most sediment moving considerable distances into riparian areas (Cooper et al. 1987), and studies that document effects of excessive sedimentation on aquatic organisms in streams bordered by wide buffers (Megahan 1987 *in* Rhodes 1994).

Setbacks of sufficient width to include the entire active floodplain prevent structures and developed land uses from impeding overbank flooding and channel migration. Setbacks including the entire active floodplain also reduce direct effects of human activities on bank stability.

Recommended Setback Width to Conserve Hydrologic and Geomorphic Functions

For the purpose of long-term conservation of hydrologic and geomorphic functions, the project team recommends that riparian setbacks include the entire active floodplain, regardless of the current extent of riparian vegetation on that surface, and that an additional 30 m (98 ft) buffer be included within the setback. This width should be sufficient to substantially slow or infiltrate much of the runoff from adjacent uplands, and to remove excessive sediment from that runoff prior to its entering the active floodplain.

It is important to note that setbacks do not ameliorate many effects of human alterations on hydrologic and geomorphic functions. Some effects are offset only if the activities causing them are excluded from the setback. Examples of these activities include riparian vegetation removal, grazing, and channel modifications. Other alterations are only partially offset, such as the effects of developed or agricultural land cover on runoff and groundwater. Finally, other effects are not addressed by riparian setbacks. These include the effects of surface water diversions, groundwater withdrawals, and dams. Therefore, to conserve hydrologic and geomorphic functions, other measures are necessary in addition to setbacks.

Chapter 3
Biogeochemical Functions

Introduction

Biogeochemical functions cycle elements among compounds and locations by biological and geological mechanisms. For example, in the carbon cycle, photosynthesizing plants remove carbon from the atmosphere; through respiration, plants, animals, and microbes return carbon to the atmosphere. A substantial quantity of carbon is stored in these organisms and in the organic matter derived from them. Nutrient cycles are essential to ecosystem functions; moreover, such cycles facilitate the transformation and degradation of contaminants entering these ecosystems.

All terrestrial habitats provide some biogeochemical functions. However, riparian areas are particularly important for nutrient and other element cycles because they are ecotones (transitional zones) between terrestrial, fluvial, and groundwater systems. Consequently, riparian areas have substantial effects on water quality because they help to regulate the transfer of sediment and water, and because they facilitate chemical transformations of contaminants (Naiman and Decamps 1997; Brinson et al. 2002).

This chapter reviews the transport, storage, and transformation of nutrients, metals, and synthetic organic compounds (SOCs; e.g., most pesticides) in riparian areas, and the consequences of human alterations for these ecosystem processes. The chapter concludes with a summary of the relationships between riparian setback widths and human influences on biogeochemical processes.

Effects of Human Alterations on Biogeochemical Functions

Macronutrients

Agricultural and developed lands are major sources of nitrogen and phosphorus entering streams and rivers (Jackson et al. 2001). In aquatic ecosystems, over-enrichment with phosphorus and nitrogen (i.e., eutrophication) causes a wide range of problems, including degradation of water quality for human uses (e.g., irrigation, drinking, recreation), toxic algal blooms, loss of biodiversity, and fish kills (Richter et al. 1997; Jackson et al. 2001). These detrimental effects are largely due to greatly increased growth of microbes, algae, and plants, accompanied by the decomposition of their biomass and the resulting depletion of dissolved oxygen (DO). DO is frequently the key substance in determining the extent and composition of life in water bodies (Manahan 1994). For instance, it was found to be one of the best environmental predictors of invertebrate community composition in flow-through constructed wetlands (Spieles and Mitsch 2000). Salmonids are particularly sensitive to low DO concentrations (Bjornn and Reiser 1991).

The cycles of phosphorus and nitrogen involve different mechanisms, and riparian areas affect these cycles differently. Accordingly, these cycles and the effects of human alteration are described in separate sections below.

Phosphorus

Ultimately, all phosphorus originates from the weathering of rock; it should be noted that different rock types may have substantially varied phosphate contents (Wetzel 2001). However, because it is a macronutrient, phosphorus concentrates in organisms; consequently, organic matter, fertilizer applications, wastes from concentrated animal feeding operations (CAFOs), and sewage are all important sources of the phosphorus entering streams (Jackson et al. 2001).

The availability of soluble phosphorus (i.e., phosphorus in a molecule dissolved in water) is strongly affected by pH (Wetzel 2001). Soluble phosphorus is most available at a pH of 6–7; consequently, it is most readily leached from soils of that pH range. At lower pH values, phosphorus combines readily with aluminum, iron, and manganese. At higher pH values, greater amounts of phosphate combine with calcium as calcium phosphates and apatites (i.e., minerals in which calcium and phosphorus combine with other elements). These reactions (that predominate above and below the pH 6–7 range) result in the formation of insoluble complexes and the adherence of phosphorus to the surfaces of clay particles.

In most environments (including waters with pH values of 6–7), insoluble forms of phosphorus predominate because they readily form and persist longer than soluble forms, which are rapidly taken up by microorganisms and plants or are sorbed to soil particles (Marschner 1995; Wetzel 2001). (Sorption includes absorption, adsorption, and physical interspersion or association.) Consequently, runoff is the primary means by which phosphorus enters waters, because most phosphorus is transported to streams adhered to soil particles or associated with particles of organic matter (Wenger 1999; Jackson et al. 2001; Wetzel 2001). Insoluble and sediment-bound forms of phosphorus may subsequently become soluble in streams.

Though phosphorus is readily bound to particles of clay and organic matter, soils cannot retain unlimited quantities of phosphorus. Therefore, high inputs of phosphorus could saturate binding sites in riparian soils. This saturation was suggested by the results of several studies (reviewed in Wenger 1999) where the percent of phosphorus inputs removed by newly established buffers declined over time.

Human alteration of ecosystems can affect the transport and storage of phosphorus in riparian areas through the effects of adjacent land uses, conversion of riparian areas to agricultural or developed land cover, hydrologic and geomorphic alterations, and alterations of riparian vegetation and soils. In addition to increasing phosphorus inputs, adjacent land uses can increase or concentrate overland flows, or even route them past riparian areas. For example, the Roseville Wastewater Treatment Plant adds effluent containing substantial quantities of phosphorus to Dry Creek (ECORP 2003), and this effluent enters the stream without ever passing through the soils of a riparian area. Such alterations limit opportunities for phosphorus to sorb to particles of clay and organic matter in the soil. Similarly, drainage tiles and ditches also reduce phosphorus retention by moving flows rapidly through riparian areas. Conversion of riparian areas to agricultural or developed land uses reduces the size of riparian areas, and thus reduces the residence time of flows and the capacity of the riparian area for retaining phosphorus. Direct alterations that reduce hydraulic roughness of the vegetation or soil infiltration (e.g., grazing, timber harvest) could reduce sediment deposition and the residence time of flows in the riparian area, which could in turn reduce phosphorus retention.

Nitrogen

Nitrogen cycling involves fixation of atmospheric nitrogen (N_2) into organic molecules, and the return of nitrogen to the atmosphere through denitrification (Jackson et al. 2001; Wetzel 2001). Microorganisms perform both these transformations. Nitrogen is also fixed by the high temperatures and pressures of internal combustion engines and, to a lesser extent, by lightning. The nitrogen fixed into organic molecules is stored in living organisms and the organic materials derived from them. It is a constituent of amino acids and nucleic acids, and is also a component of the animal waste products urea and uric acid, as well as other organic molecules. During decomposition, nitrogen is released to the environment in the small inorganic molecules ammonia (NH_4^+), nitrite (NO_2^-) and nitrate (NO_3^-). These molecules and small organic molecules (e.g., amino acids) are highly soluble, readily taken up by microbes and plants, and through denitrification are transformed to N_2 and returned to the atmosphere.

Agricultural and developed lands are major sources of the nitrogen entering streams (Jackson et al. 2001). Fertilizer applications and wastes from CAFOs are the primary sources on agricultural lands. On developed lands, nitrogen sources include septic systems, pet wastes, fertilizers applied to lawns and other landscaping, sewage systems, and some industrial sources. Erosion is also an important source of nitrogen from both agricultural and developed lands.

Unlike phosphorus, nitrogen is quite soluble and readily moves into shallow groundwater (Lowrance et al. 1984; Schnoor 1996); in many areas most nitrogen enters streams via subsurface flows (Fennessey and Cronk 1997). Denitrification is the major pathway for removal of nitrogen as this subsurface water crosses riparian areas. Plant uptake also removes nitrogen from groundwater and stores it in plant tissue (Marschner 1995; Fennessey and Cronk 1997). However, unless they are removed from riparian areas or deeply buried, plant tissues will decompose after death, releasing this stored nitrogen.

Most denitrification occurs in saturated soils (Fennessey and Cronk 1997; Jackson et al. 2001; Wetzel 2001). There, low oxygen (O_2) concentrations create a demand for NO_3^- as an electron acceptor. During aerobic respiration (the primary source of energy for the metabolic activities of animals, plants, and many microbes), oxygen is required as the terminal electron acceptor. Where limited oxygen availability hinders aerobic respiration (e.g.,, under anaerobic conditions), organisms can still derive energy from metabolic pathways that rely on other molecules as electron acceptors. In the case of denitrifying bacteria, energy is derived from organic compounds using NO_3^- instead of oxygen as the terminal electron acceptor.

Factors affecting removal of nitrates by riparian areas include the portion of flows crossing the riparian area as runoff, the rate of denitrification, and the time required for subsurface flows to cross the riparian area (Fennessey and Cronk 1997). Because surface flows cross riparian areas rapidly, little or no nitrate is removed from runoff. From subsurface flows, the amount of nitrate removed is a product of the rate of denitrification and time in the riparian area.

Rates of denitrification are governed by the following conditions.

- Nitrate concentration.
- Quantity of organic carbon.
- Degree of soil saturation.
- Activity of denitrifying bacteria.
- Temperature.
- pH.

Denitrification primarily removes nitrogen that enters riparian areas as nitrate, and low concentrations of nitrate, relative to other forms of nitrogen (e.g., organic nitrogen), can limit the rate of denitrification. For example, in one study, 76% of the nitrogen entering a riparian area was in nitrate, but only 18% of the nitrogen leaving that riparian area was in the form of nitrate (Fennessey and Cronk 1997). Compared to nitrate, a much larger fraction of nitrogen in organic compounds passes through riparian areas.

Organic matter is the substrate from which denitrifying bacteria obtain energy; consequently, the lack of a carbon source can limit denitrification. Exudates from plant roots, and the roots themselves, provide an important carbon source for soil microorganisms (Marschner 1995; Gurwick et al. 2004).

Saturated soils have higher denitrification rates than unsaturated soils because they have less oxygen availability than dry or unsaturated soils. Denitrification is a mechanism for extracting energy from organic molecules; in aerobic environments, many denitrifying bacteria will perform aerobic metabolism instead of denitrification, or will compete for carbon sources with microbes performing aerobic respiration. Aerobic respiration does not involve nitrate, and thus the rate of N_2 production decreases (Fennessey and Cronk 1997; Wetzel 2001).

The ability of denitrifying bacteria to perform denitrification depends on their abundance and the quantity of nitrate to which they have recently been exposed, which together determine the overall denitrifying activity of the microbes; temperature (which affects the rate of all reactions); and pH (Fennessey and Cronk 1997; Wetzel 2001).

The residence time of surface and subsurface water in a riparian area is as important as the rate of denitrification. Many factors affect the residence time of water in riparian areas; these include width of the riparian area, slope gradient, surface roughness, hydraulic head (i.e., the force moving water through the riparian area), and soil hydrologic connectivity (i.e., permeability) (Gordon et al. 1992; Brunke and Gonser 1997; Spruill 2000). Depending on the characteristics of the given riparian area, residence times can range from hours to months or even years. Within individual riparian areas, residence time also can vary considerably due to local concentration of flow before it enters the riparian area, heterogeneity in hydrology and topography, and the characteristic heterogeneity of the texture (and hence permeability) of riparian soils (Brunke and Gonser 1997; Fennessey and Cronk 1997).

Riparian areas typically support favorable conditions for denitrification (Fennessey and Cronk 1997; Naiman and Decamps 1997; Brinson et al. 2002). The rooting zone of riparian soils is typically saturated, and plant roots provide an organic carbon source. In addition, riparian soils support high levels of microbial activity (Fennessey and Cronk 1997; Naiman and Decamps 1997; Tufekcioglu et al. 2001; Brinson et al. 2002). Therefore, a substantial portion of the nitrates contained in subsurface flows are denitrified if they pass through the rooting zone (Pinay and Fabre 1993; Fennessey and Cronk 1997; Lee et al. 2000; Spruill 2000; Sabater et al. 2003; McKergow et al. 2004; Zegre et al. 2004).

However, not all water entering streams passes through riparian soils within the plant rooting zone, where conditions for denitrification are most favorable. For example, overland flows and deep groundwater do not pass through this zone; consequently, the riparian area may remove little nitrogen from these waters (Fennessey and Cronk 1997; Wenger 1999; Spruill 2000; Simpkins et al. 2002).

Human alterations affect the ability of riparian areas to remove nitrogen through the effects of adjacent land uses, conversion of riparian areas to agricultural and developed land cover, hydrologic and geomorphic alterations, and direct removal of riparian vegetation. Adjacent land uses can increase overland flows and nitrogen inputs, and can concentrate flows or route them past riparian areas. Increased overland flows and concentration of flows before they enter riparian areas reduces the time water spends there, and reduces their opportunity to remove nitrogen. Conversion of portions of riparian areas to developed or agricultural uses reduces the time water spends within the riparian area and hence the quantity of nitrogen removed. Artificial drainage (e.g., tile drains) also reduces the residence time of water. Flow diversions, groundwater withdrawals, and channel incision that lowers the water table below the rooting zone of riparian vegetation reduce the ability of riparian soils to remove nitrogen and the ability of plants to take up nitrogen. Riparian management that reduces infiltration, vegetation density, or the cover of woody plants can also reduce nitrogen removals by reducing flows through the plant rooting zone or by altering the density and depth of plant roots.

In western Placer County, incision of stream channels is widespread (Appendix A; Placer County 2002; ECORP 2003; EDAW 2004; Jones & Stokes 2004c), and riparian vegetation has often been reduced to a narrow discontinuous band (Appendix A; Placer County 2002). Consequently, human alterations have reduced the denitrifying capacity of these riparian areas.

Heavy Metals

Heavy metals include zinc, copper, cadmium, lead, nickel, iron, silver, chromium, and mercury. Due to their potential toxicity at low concentrations to organisms at all trophic levels, heavy metal contaminants, particularly mercury, have been identified as a problem in the Sacramento River Basin (including the Bear River in Placer County) and downstream in the Bay-Delta (CALFED 2000a). Downstream of Placer County in the Sacramento–San Joaquin Bay-Delta, relatively high (and potentially harmful) concentrations of copper, nickel, zinc, and mercury have been observed in water and in some cases in organisms (Cain and Louma 1999; Hornberger et al. 1999; CALFED 2000a). These metals can cause gill, kidney, liver, and nerve damage in fish and other aquatic organisms (Luoma et al. 1990; Schnoor 1996; Morel et al. 1998; CALFED 2000a). Because of differences in its cycling in the environment, as well as heightened concerns regarding bioaccumulation, mercury is discussed separately from the other heavy metals in this chapter.

Mercury

Mercury contamination is widespread in sediments and waters of the Sacramento Valley, including western Placer County, and downstream in the Sacramento–San Joaquin Bay-Delta. Although atmospheric deposition and inputs from developed land uses occur, mercury contamination is in large part a legacy of the

California gold mining era, when mercury was used in the gold refining process (Domagalski 1998).

The fate of mercury in the environment depends on its chemical form and the local environmental conditions (Beckvar et al. 1996). Elemental mercury, inorganic mercury, and methylmercury are the three most important forms of mercury in natural aquatic environments. Most mercury is released into the environment as inorganic mercury, which is primarily bound to sediment particles and organic substances; in this form, it may not be available for direct uptake by aquatic organisms. However, methylmercury, an extremely harmful form of mercury, is readily taken up by aquatic plants, fish, and wildlife; it has been demonstrated to bioaccumulate and transfer through the food web (Beckvar et al. 1996).

Methylmercury is formed by sulfate-reducing bacteria (Wetzel 2001). The methylation of mercury is influenced by the availability of inorganic mercury, oxygen concentration, pH, oxidation-reduction potential, presence of sulfate and sulfide, type and concentrations of complexing inorganic and organic agents, salinity, and organic carbon (Blum and Batrha 1980; Jackson 1989; Parks et al. 1989; Winfrey and Rudd 1990; Beckvar et al. 1996; Gill et al. 2002). These conditions and the biological productivity of methylating microbes are also affected by seasonal changes in temperature, nutrient supply, oxygen supply, and hydrodynamics (changes in suspended sediment concentrations and flow rates).

Methylmercury has been demonstrated to accumulate in plant and animal tissues and to transfer through the food web as contaminated food sources are consumed (Beckvar et al. 1996). Methylmercury and other associated forms of bioavailable mercury damage nervous and other tissues and cause mutations, leading to cancers and reduced survival of embryos (Birge et al. 1979; Sharp and Neff 1980; Gentile et al. 1983; Thain 1984; Morel et al. 1998; CALFED 2000a).

Sediment is the primary source of mercury entering aquatic environments in the Sacramento Valley (Beckvar et al. 1996). Correlating mercury concentrations in sediment with concentrations in biota is difficult, however, particularly for higher-trophic-level species. High concentrations of organic substances and reduced sulfur that complex with free inorganic mercury ions in sediment can reduce the availability of mercury to biota (Luoma 1977; Rubinstein et al. 1983). Many investigators report no correlation between sediment and tissue concentrations of mercury for higher-trophic-level species (Nishimura and Kumagi 1983; Jackson 1988; Rada et al. 1989b; Lindqvist 1991; Dukerschein et al. 1992). This difficulty in correlating mercury in sediment with mercury in organisms reflects the complexity of variables that affect both the methylation of mercury in surface sediments and its transfer between trophic levels (Beckvar et al. 1996).

The movement, transformation, and storage of mercury within riparian areas are particularly complex processes; the human effects on these processes are also complex. Consequently, the effects of riparian setbacks on methylmercury production are likely to vary among sites. Wide setbacks (e.g., more than 30 m

[98 ft]) would reduce inputs of mercury-laden sediments from adjacent uplands, and would reduce disturbance and remobilization of mercury-laden sediments in riparian areas. However, the saturated soils and high organic carbon content of many riparian soils provide favorable conditions for methylation of mercury; in western Placer County, such soils also likely contain some mining sediments with elevated concentrations of mercury. Therefore, riparian setbacks may reduce additional inputs of mercury to riparian areas and streams, but probably will not diminish the role of riparian areas as a source of methylmercury.

Other Heavy Metals

Heavy metals enter streams from natural and human sources. Natural sources are the dissolution of rocks and minerals in sediments. Human sources include brake pad debris (Woodward-Clyde Consultants 1994), roofing materials (U.S. Environmental Protection Agency 1978) and other urban and industrial inputs, agricultural chemicals (e.g., copper-based herbicides), historical mine tailings, and acidic mine drainage (CALFED 2000a; Paul and Meyer 2001).

Unlike SOCs, heavy metals are elements that cannot be degraded; unlike nitrate, relatively little metal is transformed into other chemical forms that volatilize into the atmosphere. Therefore, heavy metals removed from flows are merely stored in riparian areas. This storage may be transient, as when metals in overland flows rapidly cross the riparian area, or may be for prolonged periods of time, as when metals sorb to buried sediments in riparian areas.

In riparian areas and adjacent streams, metal ions may be dissolved in water (either hydrated or complexed with other ions), precipitated (i.e., in an insoluble complex), sorbed to sediment or suspended particles, or taken up by plants or microbes. With the exception of uptake by organisms, these states are reversible, and metals exist in equilibrium between them. (The concentration of metal in each state depends on its rate of conversion to other states, relative to the reverse transformation.) This equilibrium, and the concentration of metals in water, is strongly influenced by DO concentration, pH, and the abundance of organic matter (Wetzel 2001; Schnoor 1996). In anaerobic environments, metals tend to precipitate in complexes with sulfides that are generated by microbes under these conditions. Under aerobic conditions, at near neutral (i.e., pH 7) and high pH (i.e., pH greater than 7), metals tend to form precipitates (i.e., insoluble forms) with hydroxyl ions (OH^-). Therefore, solubility of metals is much greater in aerobic, acidic waters (i.e., pH less than 7). Because organic matter contains many components that complex with metals, increased concentrations of organic matter in soils and in suspended sediments reduces metal solubility.

The high biomass and organic matter content of many riparian soils contributes to the removal of metals from subsurface flows. (Riparian plants also take up metals, but they require only minute quantities of a few heavy metals as nutrients, and the root endodermis functions as a barrier that blocks most additional uptake [Marschner 1995]). Thus, riparian areas store metals that would otherwise enter streams. However, soils cannot retain unlimited quantities of heavy metals, and high inputs of metals could saturate binding sites in riparian soils. The clay and organic matter content, and pH, of riparian soils will substantially influence the quantity of metals they can retain.

The association of metals with the surfaces of sediments and suspended particles is particularly important for their transport and storage in riparian areas. Surfaces of particles, such as clays, are typically charged or polar, and these particles interact with a coating of ions and molecules removed from and reentering the surrounding water. In most environments, heavy metals tend to form surface complexes with particles, and this tendency has been described as “metals scavenging” by particles (Schnoor 1996).

Because of the insoluble precipitates and complexes with particles formed by metals, eroding sediments are the major delivery mechanism for metals into riparian areas. The high surface roughness and soil permeability of many riparian areas causes deposition of metal-containing sediments that would otherwise enter streams. However, this storage is not necessarily permanent. Metals may be subsequently leached from these transported sediments, and the sediments themselves may be subsequently eroded or moved by floodwaters. Riparian soils cannot retain an unlimited quantity of heavy metals (similar to soil limitations regarding phosphorus retention), and high inputs may saturate the available binding sites.

Human alterations can affect the transport and storage of heavy metals in riparian areas through the effects of adjacent land uses, conversion of riparian areas, direct hydrologic and geomorphic alterations, and direct alterations of riparian vegetation. In addition to increasing metal inputs, human alterations of adjacent lands (e.g., acid mine drainage) can increase the acidity of waters and the leaching of metals from riparian sediments. Adjacent land uses can also increase or concentrate overland flows, or even route them past riparian areas. These alterations limit opportunities for heavy metals to sorb to particles of clay and organic matter in the soil. Similarly, drainage tiles and ditches reduce metal retention by moving flows rapidly through riparian areas. Conversion of riparian areas to agricultural or developed land uses reduces the size of riparian areas, and consequently reduces the residence time of flows and the capacity of the riparian area for retaining heavy metals. Direct alterations that reduce hydraulic roughness of the vegetation or soil infiltration could reduce sediment deposition and the residence time of flows in the riparian area, also reducing metal retention.

Synthetic Organic Compounds

SOCs include most pesticides and herbicides and a wide variety of chemicals used in industry. Many of these artificial compounds persist in the environment for prolonged periods (in some cases for decades), and some (e.g., polychlorinated biphenyls [PCBs]) bioaccumulate in animal tissues (Schnoor 1996). (Use of some of the most persistent molecules has been banned, but the compounds have remained in the environment.)

Pesticides (including diazinon, carbofuran, and chlorpyrifos), herbicides, solvents, and other SOCs are frequently washed into the Sacramento Valley's river systems during irrigation, by winter storms, and through urban runoff (Kuivila and Foe 1995; MacCoy et al. 1995; Domagalski 1996). These compounds can have direct and indirect harmful effects on soils and aquatic organisms including microorganisms, invertebrates, and vertebrates (CALFED 2000a). For example, diazinon, an organophosphate insecticide used for many agricultural applications, and until recently for urban applications as well, is highly toxic to birds, terrestrial insects, aquatic invertebrates, soil microbes, and fish (Ingham and Coleman 1984; Stone and Gradoni 1985; Mackenzie and Winston 1989; Robertson and Mazzella 1989; Turner 2002). Application of this insecticide coincides with the rainy season in California, resulting in runoff discharges into streams and rivers. Consequently, in tributaries of the Sacramento River (including the Bear River in Placer County), peak values of diazinon can exceed state or federal water quality standards by an order of magnitude or more (Turner 2002).

The SOCs in streams and rivers may come from point and nonpoint sources, release of materials stored in sediments, illegal dumping, and accidental spills. Applications of pesticides and herbicides to plants and soils in agricultural and developed lands are particularly important sources of SOCs. When applied by field equipment, aerial drift may distribute them for several meters beyond the site of application (de Snoo and de Wit 1998); when these compounds are applied by airplanes, drift may extend much further (tens to hundreds of meters).

In the environment, SOCs can volatilize (i.e., disperse into the atmosphere), dissolve in and be transported by water, adsorb to soil, bioaccumulate in animals, and degrade. The fate of these compounds is determined by their chemical properties, especially their size and solubility in water. Synthetic organic compounds vary widely in size and polarity. Many SOCs contain highly polar alcohol, organic acid, and ionic groups that increase their polarity, and increase their solubility in water. However, other SOCs are essentially non-polar; these are generally insoluble. For example, the solubility in water of PCBs and dichlorodiphenyltrichloroethane (DDT) is low (approximately 10^{-2} μmoleL^{-1}); that of chlorpyrifos is higher (about 1 μmoleL^{-1}); whereas the solubility of industrial solvents such as toluene and tetrachloroethylene is very high (>10^{3} μmoleL^{-1}).

The smallest SOCs (e.g., organic solvents) are those most prone to volatilize. However, larger molecules that are relatively insoluble in water also volatilize at moderate rates (Schnoor 1996).

SOCs also sorb to particles of soil and organic matter. This sorption occurs through electrostatic attractions, ionic bonding, or physical intermingling (e.g., the dissolution of a non-polar molecule among particles of organic matter). However, stronger and less reversible chemical bonds also may form. The tendency of an SOC to sorb to sediment is negatively related to its solubility in water (i.e., molecules with lower solubility in water have greater propensity to sorb to sediment). The sorbed molecules of SOCs attach primarily to clays and particles of organic matter, and the sorption of SOCs increases substantially with the concentration of organic matter in the sediment (Schnoor 1996; Neitsch et al. 2002).

The accumulation of SOCs in organisms (i.e., bioaccumulation) represents the net balance resulting from uptake across gill and skin, ingestion from food, metabolic degradation, and excretion. The SOCs most prone to bioaccumulate are the relatively non-polar, hydrophobic molecules (e.g., DDT, PCBs, chlordane) that tend to sorb into membranes and fatty tissues (Schnoor 1996). Typically, these are the same molecules that tend to sorb to sediment.

SOCs can be degraded (changed into other molecules) through the absorption of light energy (photodegradation), by reacting with water or chemicals in water or soil (chemical degradation), or by microorganisms (biodegradation). With the exception of photodegradation, these processes occur most rapidly in soil (Brinson et al. 2002; Neitsch et al. 2002). Biodegradation occurs because microorganisms use SOCs as food sources; they obtain energy stored in the chemical bonds of SOCs through a series of oxidation-reduction reactions, ultimately breaking the SOCs down to carbon dioxide and water. Microbes also mediate other transformations of SOCs (Schnoor 1996). Rates of degradation of SOCs vary over a wide range (Schnoor 1996). Chemical degradation of molecules dissolved in water can reduce the concentration of some SOCs by half within minutes, while other SOCs require years before concentrations are halved. Photodegradation can break down more than 99% of dissolved Carbaryl in a month, but does not eliminate 1% of DDT in a year. For any given SOC, biodegradation rates vary with the environmental conditions listed below.

- Temperature.
- Concentration of oxygen.
- Nutrient availability.
- Microbial population density or biomass concentration.
- Acclimation of the microbial flora to the SOC.

All these factors affect the activity of microbes that perform biodegradation. Riparian areas are considered to support high rates of biodegradation because they typically contain a range of oxygen and nutrient availability, and they support dense, active populations of microorganisms (Fennessey and Cronk 1997; Naiman and Decamps 1997; Tufekcioglu et al. 2001; Brinson et al. 2002).

Overall, the degradation of SOCs in riparian areas depends not only on degradation rates but also on the infiltration of water and associated SOCs into the soil and the time required for water to cross the riparian area. Because overland flow (i.e., runoff) crosses riparian areas rapidly, little or no degradation or storage occurs (Neitsch et al. 2002; Popov and Cornish 2004). Factors affecting the passage of subsurface flows through a riparian area include its width, hydraulic head, and hydrologic conductivity (Fetter 1994; Brunke and Gonser 1997).

The degradation and storage of SOCs in riparian areas is entirely dependent on human alterations because they are the sole source of SOCs. In addition to generating inputs, human alterations also affect the degradation and storage of SOCs in riparian areas by converting these areas to other land-cover types; reducing infiltration of water in riparian areas and adjacent uplands; and lowering groundwater levels through groundwater withdrawals, flow diversions, and stream channel incision. All these alterations reduce the quantity of SOCs passing through riparian soils and the time they remain there. Alterations that concentrate overland flows, or that reduce the hydraulic roughness of riparian vegetation, can also reduce the deposition of SOCs associated with suspended sediment. In western Placer County, incision of stream channels and loss of riparian vegetation have reduced the ability of riparian areas to degrade SOCs.

Relationships Between Effects and Setback Width

A substantial quantity of research has been conducted worldwide on the biogeochemical functions of riparian areas, the effects of human alterations on those functions, and the benefits of managed buffers between streams and areas of timber harvest, agricultural activities, and development (Correll 2003). This research strongly supports the conservation and management of riparian areas and adjacent uplands for water quality benefits, and it has identified the factors affecting riparian functions. Accordingly, this research provides justification for riparian setbacks and some information to guide their planning and design. Nonetheless, current understanding is not sufficient to reliably determine the exact effects that different width buffers will have on biogeochemical functions (and stream water quality). Several computer models have recently been developed that could be used to evaluate the consequences of different width setbacks (Lowrance et al. 2000; Dallo et al. 2001; Zhongwie and Wong 2004). However, these models have several deficiencies: they have not been tested under a range of conditions; they have several unresolved issues regarding their accuracy; and they are currently costly to apply (Inamdar 2004).

The most important factors affecting biogeochemical functions in riparian areas are listed below.

- Loadings from adjacent uplands.
- Partitioning of runoff between overland and subsurface flow.
- Distribution (i.e., spatial concentration) of overland flow.
- Depth of shallow groundwater.
- Time that water resides in the riparian area or buffer (i.e., residence time).
- Quantity of sediment eroded and transported to riparian areas.
- Redistribution of deposited sediment by subsequent floodwaters.

The width of riparian setbacks can affect several of these factors, and can consequently affect the biogeochemical functions of riparian areas. First, the width of a setback determines the distance between stream waters and sources of macronutrients, metals, and SOCs. A wide riparian zone increases infiltration (and subsurface flows), rates of sediment deposition, and the time required for materials to reach a stream. Thus, greater setback widths tend to increase the storage and removal of materials en route to streams. Second, the area of sources for macronutrients, metals, and SOCs is reduced by wider setbacks because more land is retained in natural vegetation. Third, if a riparian setback extends beyond the stream's active floodplain, then sediments and associated contaminants will be stored, at least in part, outside the active floodplain, where they are less likely to be carried into streams by floodwaters.

Researchers have documented substantial reductions in stream loadings of macronutrients, metals, and SOCs due to riparian areas or buffers ranging in width from several to more than a hundred meters. (Castelle et al. 1992; Fennessey and Cronk 1997; Wenger 1999; Brinson et al. 2002.) Reductions resulting from a very narrow riparian area (e.g., 6 m [20 ft]) in one study may be comparable to reductions in a much wider riparian area (e.g., 30 m [98 ft]) in another study. This variability reflects both differences in site attributes that affect movement, transformation, and storage of these materials, as well as variability in the methods of researchers.

Overall, the most significant factors causing variation in the biogeochemical functions of riparian areas are hydrologic conditions (e.g., the depth of subsurface flows); climate and vegetation attributes seem to cause lesser effects (Fennessey and Cronk 1997; Simpkins et al. 2002; Sabater et al. 2003). Nonetheless, California's Mediterranean climate may reduce a setback's effectiveness relative to a setback of similar width in other climates. In northern California, because rainfall is concentrated during the winter months and evapotranspiration is low at that time, rain frequently falls on saturated soils, and overland flows are consequently greater than they might be under a different climatic regime.

Variation in the results of relevant research is often due to differences in the types of sites and the range of conditions included in the study. For example, many studies are conducted in small-scale plots with simulated rainstorms. The results of such short-term studies under a narrow range of conditions often indicate greater effectiveness of narrow buffers or setbacks than do the results of longer-term, larger-scale studies (Castelle et al. 1992; Davies and Nelson 1994; Fennessey and Cronk 1997; Wenger 1999; Lee et al. 2000; McKergow et al. 2004; Zegre et al. 2004). Similarly, actively managed buffers, such as tilled and planted borders of agricultural fields, are generally more effective at narrower widths than are unmanaged setbacks; appropriately, many of the recommendations for narrower setbacks are intended for actively managed areas (Lowrance et al. 2002).

Recommended Setback Width to Conserve Biogeochemical Functions

For the purpose of long-term conservation of biogeochemical functions, the project team recommends that riparian setbacks include the entire active floodplain, regardless of the current extent of riparian vegetation on that surface, and that an additional 30-m (98-ft) buffer be included in the setback.

For effective long-term conservation of riparian functions, setback widths should be sufficient to retain macronutrients, metals, and SOCs from the concentrated flows and infrequent events (e.g., intense rain on saturated soils) that transport a substantial portion of the sediment and materials to riparian areas. This criterion requires a setback of moderate width. Consequently, for the purpose of long-term conservation, though widths from several to more than a hundred meters have been recommended, setbacks of 20–30 m (66–98 ft) have been recommended most frequently (Castelle et al. 1992; Johnson and Ryba 1992; McCauley and Single 1995; Fennessey and Cronk 1997; Herrone and Hairsine 1998; Wenger 1999; Lowrance et al. 2002; Environmental Law Institute 2003; Lee et al. 2004).

It is important to note that setbacks do not ameliorate many effects of human alterations on biogeochemical functions. Not all inputs (of macronutrients, metals, SOCs, and other contaminants) to streams will pass through riparian soils (e.g., deeper groundwater flows, stormwater, and agricultural drainage that crosses in pipes or ditches). Moreover, riparian setbacks will not retain all inputs of fertilizers, heavy metals, pesticides, and other contaminants that pass through them. In addition, high levels of inputs may cause the effectiveness of setbacks to may diminish over time. Therefore, other measures that address the upland sources of macronutrients, metals, SOCs, and other contaminants are necessary.

Chapter 4
Salmonid Habitat Functions

Overview

Chinook salmon (*Oncorhynchus tshawytscha*) and steelhead (*O. mykiss irideus*) are anadromous fishes that spend a major portion of their lives in the Pacific Ocean. Maturing adult steelhead and Chinook salmon migrate from the ocean to spawn in Central Valley rivers and creeks, including those of western Placer County. After rearing in these rivers, the juveniles migrate back to the Pacific Ocean.

Salmonids occupy the freshwater systems from the Sacramento–San Joaquin Delta (Delta) to stream headwaters, depending on the streams' accessibility to migrating fish and the availability of spawning and rearing habitat within them. Not only are salmonid habitat functions valued directly, but they also provide an indicator of human effects on other components of these aquatic ecosystems. This chapter describes salmonid habitat functions and how human alterations affect those functions. It concludes with a summary of the relationships between riparian setback width and human effects, and offers the project team's recommendation for setback widths to conserve salmonid habitat functions.

Effects of Human Alterations on Migration

Shallow water depth, high water velocity, and physical barriers may impede salmonid passage through spawning streams. Human alterations affect each of these potential impediments to migration.

Water Depth

In general, water depth greater than 0.3 m (1 ft) is needed to allow passage of adult and juvenile Chinook salmon and steelhead (California Department of Fish and Game 2001; National Marine Fisheries Service 2001). However, this minimum depth may be a somewhat conservative estimate, because Chinook salmon and steelhead can pass through short sections of water that are less than 0.3 m (1 ft) deep (Thompson 1972 *in* Bjornn and Reiser 1991).

Low streamflows and shallow water depths may delay or block migrating salmonids' access to upstream spawning habitats, expose adult fish to water temperatures detrimental to individual survival, and reduce the fecundity of females (i.e., egg viability). Delayed passage of adults may also delay spawning and extend incubation of eggs and rearing of juveniles into months when warmer water temperatures predominate. The result may be reduced egg and juvenile survival and reduced productivity in that year (i.e., year class production).

Low streamflows can also affect juvenile migration. Like the requirements for adult salmonid passage, water depth greater than 0.3 m (1 ft) is necessary for passage of juvenile Chinook salmon and steelhead (California Department of Fish and Game 2001; National Marine Fisheries Service 2001). Delayed or blocked passage of juveniles may prevent access to downstream rearing habitat and increase their exposure to warm water temperatures, entrainment in diversions, and predation. The resulting decrease in survival and growth rates reduces year class production and potentially reduces adult abundance in subsequent years.

Relatively shallow flow in combination with physical barriers and high water temperatures can cause fish to fatigue as they migrate upstream; these cumulative effects may lower the survival and reproductive success of individual fish (Gallagher 1999). For these reasons, long stretches of river with maximum depths near 0.3 m (1 ft) may be barriers to migration. Other factors interacting with the effects of depth include cover and suitable resting areas (e.g., deep pools).

Flow rates may affect travel time for juvenile salmonids. Travel time for juvenile Chinook salmon and steelhead generally decreases with increasing flow and water velocities. Faster travel times may reduce exposure to predation and facilitate movement of smolts to the ocean (Berggren and Filardo 1993).

Vertical Drops

In addition to adequate depth and velocity, vertical drops should not exceed the leaping abilities of Chinook salmon and steelhead. The ability to jump vertical drops is greatly affected by staging pool depth, jump angle, and the horizontal distance of the leap (Powers and Orsborn 1985; Reiser and Peacock 1985). The ratio of staging pool depth to barrier height should be at least 1.5 (Stuart 1962; U.S. Forest Service 1977; Robison et al. 1999). Although the conservative vertical limit for adult fish is 1.4 m (4.5 ft) for steelhead and 0.9 m (3 ft) for Chinook salmon, passage is best facilitated by drops of 0.3 m (1 ft) or less. For juvenile salmonids, downstream migration is facilitated by drops of 0.15 m (0.5 ft) or less (National Marine Fisheries Service 2001).

Water Temperature

Warm temperatures and low DO concentrations may impede salmonid migration. Temperatures warmer than 13º Celsius (C) (55ºFarenheit [F]) have caused mortality of female adult Chinook salmon prior to spawning, and migration was blocked when water temperature reached 21ºC (69.8ºF) in the Delta (Andrew and Green 1960 *in* Raleigh et al. 1986; Hallock 1970 *in* McCullough 1999). In the Columbia River, a temperature of 21ºC (69.8ºF) was lethal to steelhead acclimated to a river temperature of 19ºC (66.2ºF). The response to warm temperatures may be complicated by low DO concentrations. In the Delta, adult Chinook salmon avoided temperatures warmer than 19ºC (66ºF) when DO was less than 5 milligrams per liter (mg/l) (Alabaster and Hallock 1988, 1970 *in* McCullough 1999).

Discussion of Effects

Construction of dams and other barriers, such as temporary diversion structures, are the most significant human alterations affecting migration and causing the loss of salmonid habitats (Yoshiyama et al. 2001). These barriers prevent Chinook salmon and steelhead migration to the higher foothill reaches of many streams in the Sacramento Valley. The alteration of flows, temperatures, and water quality below major reservoirs may also interfere with salmonid migration.

In western Placer County, dams are considerable impediments to fish passage. There are approximately thirty dams on western Placer County's streams (DWR 2002; Placer County 2002; Bailey Environmental 2003). While some of these allow fish passage under many flow conditions, others (e.g., Cottonwood Dam on Miners Ravine) are more substantial barriers.

Water control structures, road crossings, and culverts constrain flows and can create high water velocities. Culverts are characteristically uniform and designed to optimize flow efficiency, often resulting in high velocities. The velocity a fish can overcome in moving through a culvert depends on its length; as culvert length increases, flow velocities must decrease to permit fish passage. In general, water velocity should be less than 1 meter per second (m/sec) (3 feet per second [ft/sec]) for any culvert more than 30 m (98 ft) long and less than 1.5 m/sec (5 ft/sec) for culverts less than 30 m (98 ft) long (California Department of Fish and Game 2001). In western Placer County, roads cross streams at dozens of locations, and the culverts under a number of these roads are partial barriers, particularly at low flows (DWR 2002; Placer County 2002; Bailey Environmental 2003).

Surface water diversions and management of water releases from reservoirs can affect migration and increase mortality of juvenile salmonids by creating warm water temperatures. Diversions also can cause direct effects such as migration delay, injury, and mortality resulting from entrainment, impingement, and predation (National Marine Fisheries Service 1994). Entrainment occurs when fish move with the diverted flow into a canal or turbine; in most cases, entrained organisms do not survive. Impingement occurs when individual fish come in contact with a screen, a trashrack, or debris at the intake. Contact causes bruising, loss of scales, and other injuries. Fish mortality can result if impingement is prolonged, repeated, or occurs at high velocities. In addition, intakes increase predation by stressing or disorienting prey fish and by providing habitat for fish and bird predators (National Marine Fisheries Service 1994).

The proportion of a population that can become entrained or impinged in diversions depends on the location, timing, duration, and volume (relative to total flow) of the diversion relative to the distribution, abundance, and behavior of each species' life stage. Diversions in the Sacramento River Basin affect juvenile Chinook salmon and steelhead (U.S. Fish and Wildlife Service 1995). In addition to the possibility of entrainment at unscreened diversions, juvenile salmonids can be impinged against screens by fast-moving water, or they can pass through screens that are not designed to screen out salmonid fry and other small fish. Western Placer County's dams are associated with water diversions. Most of these diversions are unscreened, and thus entrainment can occur.

Effects of Human Alterations on Spawning Habitat

Salmonids lay their eggs in streambed gravels. The fish create depressions in the gravel, deposit and fertilize their eggs, and then bury the eggs with gravel. The resulting gravel nest is called a redd. The quality of spawning habitat is influenced by water temperature and depth, flow velocity, and substrate.

Water Temperature

Chinook salmon eggs and larvae require temperatures between 4ºC and 12ºC (39.2ºF and 53.6ºF) for maximum survival (Myrick and Cech 2001). Survival of eggs was less than 50% when temperature is warmer than 16ºC (60.8ºF) (Alderice and Velsen 1978). Optimal water temperatures for steelhead spawning and incubation are similar to those of Chinook salmon; they fall between 3.9ºC and 11.1ºC (39ºF and 52ºF) (Myrick and Cech 2001). Steelhead eggs subjected to temperatures warmer than 15ºC (59ºF) are prone to increased mortality.

Water Depth and Velocity

Water depth and flow velocity are factors that influence spawning habitat selection for Chinook salmon and steelhead. Minimum water depths at redd areas vary with fish size and water velocity, because these variables affect the depth necessary for successful digging; the water should be sufficiently deep to cover the fish (Healey 1991). In general, suitable spawning gravels are covered by flows at least 0.25 m (0.8 ft) deep and with velocities between 0.25 m and 1.2

m/sec (0.8 and 3.8 ft/sec) (Bjornn and Reiser 1991; Railegh et al. 1986). Reduced flows during incubation periods may cause mortality through desiccation of redds, or through reduced water circulation resulting in low DO, accumulation of metabolic waste, and increased incidence of disease.

Substrate

Although the suitability of gravel substrates for spawning depends largely on the species and individual fish size, a number of studies have determined substrate sizes that represent the most suitable conditions. Generally, Chinook salmon require substrates of approximately 0.3–15 cm (0.1–5.9 inches), whereas steelhead prefer substrates no larger than 10 centimeters (4 inches) (Bjornn and Reiser 1991).

The eggs depend on water flow through spawning gravels to supply oxygen for the developing embryos. Oxygen is supplied by the water flowing through the area of the gravel bed with the eggs (i.e., the redd). Flow rates and the concentration of oxygen in the flowing water effectively determine the DO available to eggs and fry in the redd.

The velocity of the water and the permeability of the surrounding gravels together determine the rate at which water flows through a redd. Gravel beds consisting of smaller-sized particles have lower permeability (greater resistance) to water flow than do gravel beds consisting of larger-sized particles. Therefore, the velocity of water through a redd slows as particle size decreases.

Discussion of Effects

Throughout the Central Valley, including Placer County, human alterations (i.e., changes in sediment supply and transport) have substantially reduced the extent of suitable spawning gravel for salmonids (Jones & Stokes 2004c). Along most Central Valley rivers and streams, sediment supply and transport have been altered by hydraulic mining, levees, land use changes, gravel mining, dam construction, and water diversions (CALFED 2000b). Currently, managed forest lands, roads, construction, and developed and agricultural lands contribute substantially more sediment than do areas of natural vegetation (Charbonneau and Kondolf 1993). In the lower portions of watersheds, most of this sediment is of fine materials (less than 2 mm [0.08 in] in diameter). On most rivers and streams, dams block the transport of coarser materials from the upper portions of watersheds, while gravel mining has removed coarse materials from downstream floodplains and channels. As a consequence of these changes, spawning habitats for Chinook salmon and steelhead have been reduced.

The addition of fine sediments into streams and streambeds can decrease the quality and quantity of spawning habitat by reducing the permeability of spawning gravels and thus reducing the flow of water and oxygen to eggs, which leads to direct mortality of eggs and fry, physiological stress, and impediments to the movement of fry from the redd (Gibbons and Salo 1973; Tappel and Bjornn 1983, Sigler et al. 1984; Raleigh et al. 1986; Lloyd et al. 1987; Reynolds et al. 1989; Waters 1995; Ligon et al. 2003). In western Placer County, gravel beds currently have high concentrations of fine sediments that reduce suitability for spawning (Jones & Stokes 2004b).

Spawning habitats are also affected by human alterations of riparian vegetation. The loss of riparian vegetation has contributed to increased water temperatures and reduced quality of spawning habitat along many Central Valley rivers and streams, including those in western Placer County (CALFED 2000b; Jones & Stokes 2004b). Reduced flows may allow riparian vegetation to establish on river bars and channels where establishment and survival were not previously possible because of scouring or prolonged submergence under unregulated flow regimes (Pelzman 1973). This encroachment of vegetation stabilizes sediments and confines the channel, contributing to a reduction in salmonid spawning habitat.

Effects of Human Alterations on Rearing Habitat

Multiple environmental conditions, food resources, and interactions among individuals, predators, and competitors all influence rearing habitat quantity and quality and the productivity of streams (Bjornn and Reiser 1991). Water temperature and velocity, cover, and inundation of floodplains are particularly important factors influencing salmonid rearing habitats.

Water Temperature

Water temperature has a strong affect on juvenile salmonids, and rearing success deteriorates at water temperatures above 20ºC (68ºF) (Raleigh et al. 1984; Myrick and Cech 2001). Myrick and Cech (2001) observed maximum juvenile growth rates at water temperatures between 17ºC and 20ºC (62.6ºF and 68ºF) and at 19ºC (66.2ºF), for steelhead and Chinook salmon, respectively. Rich (1987) found that juvenile Chinook salmon from the Nimbus State Fish Hatchery died before the end of the experiment when reared at 24ºC (75.2ºF). Steelhead juveniles can be expected to show significant mortality at temperatures exceeding 25ºC (77ºF) (Raleigh et al. 1984; Myrick and Cech 2001).

Water Velocity

Water velocity is of particular importance in determining where juvenile salmonids occur, because it determines the energetic requirements of fish for maintaining position and the amount of food delivered to a particular location. Juvenile salmonids tend to select positions that maximize access to food and minimize energy expenditures, but these positions can be altered by interaction with other fish and the presence of cover (Shirvell 1990). The water velocity preferred by salmonids varies with size of the fish; larger fish occupy areas of higher velocity and greater depth than small fish, potentially gaining access to abundant food and avoiding predatory birds (Bjornn and Reiser 1991; Jackson 1992). Griffith (1972 *in* Raleigh et al. 1984) found water velocities of 0.10–0.22 m/second (sec) (0.32–0.72 ft/sec) to be associated with occurrence of rainbow trout. Sheppard and Johnson (1985) found similar results for juvenile steelhead; they measured velocities of 0.12–0.24 m/sec (0.40–0.80 ft/sec). Bovee (1978 *in* California Department of Fish and Game 1991) reported water velocities of 0.18–0.37 m/sec (0.6–1.2 ft/sec) as the preferred range for juvenile rainbow trout and steelhead.

Cover

Instream cover (e.g., undercut banks, downed trees, other woody debris) is important for juvenile rearing. The addition of cover increases spatial complexity and may reduce predation of juvenile fish. The abundance of food, suitable physical conditions, and the presence of competitors and predators determine cover value. Fine-textured instream woody material provides the hydraulic diversity necessary for selection of suitable velocities, access to drifting food, and escape refugia from predatory fish. An area of cover less than 15% of the total habitat area is likely inadequate for juvenile salmonids (Raleigh et al. 1984).

Shaded riverine aquatic (SRA) cover is important to juvenile Chinook salmon and steelhead because it provides high-value resting and feeding areas and protection from predators. Riparian vegetation not only provides woody debris for instream cover, but also filters sediments, inputs organic matter, modifies channel pattern and geometry, creates SRA cover, and provides habitat for aquatic invertebrates eaten by salmonids. For these reasons, stream sections shaded by riparian vegetation (in contrast to sections characterized by denuded banks) provide important rearing and resting areas for adult Chinook salmon and steelhead migrating upstream (Raleigh et al. 1984, 1986; Slaney and Zaldokas 1997; Haberstock 1999; CALFED 2000b). Woody material is important not only because it provides instream cover, but also because it affects geomorphology and facilitates the creation of pools for holding juvenile salmon during high flow events (Larson 1999; Macklin and Plumb 1999). Shade reduces daily temperature variability and maximum temperature, maintains DO, and may help maintain base flows during dry seasons (Slaney and Zaldokas 1997; Whitting 1998; Haberstock 1999; CALFED 2000).

Floodplain Habitat

Seasonally inundated floodplains, though they provide habitat for both native and nonnative fish species, are particularly important to native species (Moyle et al.

2000). Many native fish species, including salmonids, are dependent on or benefit from inundated floodplains. Floodplains function as nursery areas, refuges from low water temperatures in early spring and winter, and refuges from high water velocities during high flow periods (Turner et al. 1994). Inundated floodplains also provide high food abundance, a range of water temperature conditions, and increased water clarity that may increase growth and survival rates (Sommer et al. 2001a, 2001b). Inundated floodplains of the Sacramento River and its tributaries may also provide high-quality organic nutrients to the Bay-Delta, benefiting estuarine species.

Discussion of Effects

Human alterations have affected rearing habitat by reducing water quality, removing riparian vegetation, hydraulically isolating floodplains, and altering flows. The introduction of nonnative predatory fish species has also detrimentally affected juvenile rearing. These alterations have all contributed to the loss of rearing habitat in western Placer County.

Adjacent agricultural and developed land uses are sources of contaminants and sediment (e.g., macronutrients, pesticides, and heavy metals) that reduce water quality. These effects on water quality are described in the chapter dealing with biogeochemical functions.

In addition to physically affecting salmonids, contaminants and sediments can cause changes in macroinvertebrate communities. These changes in turn can affect food available to foraging fish (Waters 1995). Such changes may have occurred in the streams of western Placer County, because in all six streams for which data are available, macroinvertebrate communities are dominated by species moderately to highly tolerant of pollution (Bailey 2003).

Researchers have found that elevated concentrations of suspended sediment can cause direct mortality of fry, fingerlings, and juvenile salmonids (Sigler et al. 1984; Lloyd et al. 1987; Reynolds et al. 1989). Sublethal effects include avoidance of sediment-laden areas, reduced feeding and growth, respiratory impairment, reduced tolerance to disease and toxicants, and physiological stress (Waters 1995).

The loss of riparian vegetation and SRA cover results from conversion of riparian areas to other land uses, adjacent gravel mining, placement of bank protection (e.g., riprap), grazing, and other direct removals (e.g., due to levee maintenance). It also is a consequence of hydrologic and geomorphic alterations, such as flow reductions and incision. Because riparian vegetation affects not only stream water temperature, but also cover, food resources, habitat complexity, and geomorphic processes (e.g., pool formation, bank stability), its loss substantially degrades rearing habitat. In western Placer County, conversion to developed or agricultural land-cover has removed extensive areas of riparian vegetation (Jones & Stokes 2004a, 2004b), and remaining vegetation is often in narrow bands with a discontinuous cover of trees (Appendix A).

Water diversions cause broad effects on stream ecosystems that can reduce the quality of rearing habitat. Water diversions affect fish, aquatic organisms, sediments, salinity, streamflows, habitat, foodweb productivity, and species abundance and distribution (National Marine Fisheries Service 1994). Some diversions have screens that exclude larger organisms such as most adult fish, but eggs, larvae, invertebrates, plankton, organic debris, and dissolved nutrients are important components of the lower trophic levels that may be lost to diversions. Reductions at the lower trophic levels can result in reduced food supplies and have secondary impacts on all higher trophic levels, affecting the overall foodweb. In western Placer County, there are over two dozen water diversions, and most of these are unscreened (DWR 2002; Placer County 2002; Bailey Environmental 2003; Jones & Stokes 2004b).

Human alterations affecting hydrologic and geomorphic processes can reduce rearing habitat on floodplains. (The effects of human alterations on hydrologic and geomorphic processes are described in detail in the chapter on hydrologic and geomorphic functions.) These alterations include water diversions, groundwater withdrawals, dams, levees, bank protection, and changes in land cover. Due to human alterations, in western Placer County, stream channel incision has reduced the area of rearing habitat on floodplains.

In addition to inundating floodplains, streamflow has several effects on the rearing capacity of streams. Predation may increase during low flows, particularly during downstream migration of juveniles. Higher flows result in faster outmigration, reduced water clarity, and cooler water temperature, all contributing to reduced predation (U.S. Fish and Wildlife Service 1996). Both flow and depth affect travel time for juvenile salmonids. Faster travel time may reduce exposure to predation and facilitate movement of smolts to the ocean (Berggren and Filardo 1993).

Flow alterations have a major effect on the water temperatures of Sacramento Valley streams. For rivers and larger streams, reservoir operations (i.e., the timing, temperature, and magnitude of reservoir releases, as well as total reservoir storage) are among the most important influences on water temperatures. Agricultural and municipal diversions reduce river flow and potentially increase temperatures during summer months (Myers et al. 1998; Myrick and Cech 2001), and the elevated temperatures of irrigation return flows can also affect instream water temperatures (U.S. Fish and Wildlife Service 1995). Water temperatures that are marginal or unsuitable for rearing of juvenile salmonids frequently occur along most streams in western Placer County (Bailey 2003; Jones & Stokes 2004b).

Streamflow also affects the concentration, and consequently the detrimental effects, of contaminants. For example, experimental studies indicated that contaminants in agricultural return flow from the west side of the San Joaquin Valley had no detrimental effects on the growth and survival of juvenile Chinook salmon when the return flows were diluted by 50% or more with San Joaquin River water (Saiki et al. 1992).

High pesticide concentrations may affect aquatic invertebrates (Brown et al. 2000). Adult and larval aquatic macroinvertebrates are a major food source for juvenile Chinook salmon, and a loss of invertebrate production could have an effect on juvenile salmonid production (Brown and May 2000); however, the extent of this effect has not been quantified.

Rapid fluctuations in flows can cause the stranding of juvenile and adult anadromous fish and the dewatering of redds. Fish can become stranded in borrow areas, the floodplain, shallow nearshore areas, side channels, and deep areas in the active stream channel when water levels change quickly.

Although adult fish do become stranded, juvenile fish are more vulnerable to stranding. Fry are poor swimmers and tend to stay in shallower water along the edges of streams and rivers or in side channels (Phinney 1974; Woodin 1984; Hunter 1992). Juvenile fish are not as able to follow receding waters back to the river (U.S. Fish and Wildlife Service 1995b). Also, redd dewatering can occur when flows decline while eggs are incubating.

Factors such as the total drop in stage, the lowest water level attained, the frequency of flow reductions, and the rate of change in flow affect fish stranding rates. In an episode of flow reduction, the greater the total drop in stage, and the lower the lowest flow attained, the more likely it is that side channels and shallow ponds in the floodplain will be isolated from flow and that gravel bars where redds may be located could be exposed (Hunter 1992). Frequent flow fluctuations result in cumulative stranding (U.S. Fish and Wildlife Service 1995; Bauersfeld 1978), and the faster the rate of change in flow, the more likely fish are to become stranded. Olsen (1990) found that ramping rates of less than 2.5 cm per hour (1 inch per hour) were needed to protect steelhead fry on the Sultan River in Washington State.

Relationships Between Setback Width and Effects of Human Alterations

The width of riparian setbacks directly affects the integrity of geomorphic processes that sustain salmonid habitats, the area of floodplain rearing habitat, and the extent of riparian vegetation providing SRA cover and inputs to the aquatic ecosystem. Setback width also influences inputs of sediment and contaminants from adjacent uplands; these inputs are described in other chapters (Chapters 2, 3, and 5) of this report.

Structures, developed land uses, and most agricultural land uses within the active floodplain detrimentally affect salmonid habitat functions. Thus, to conserve salmonid habitat functions, setback widths should be sufficient to include the active floodplain and to buffer the active floodplain from detrimental effects that may result from adjacent land uses.

All riparian vegetation within the active floodplain contributes inputs to the aquatic ecosystem. These inputs are greatest from vegetation immediately adjacent to the stream channel, and shade is only provided by vegetation within a distance determined by stream orientation, tree height, and topography. In some cases (e.g., topographically confined or incised reaches), the vegetation affecting streams is outside the active floodplain. One tree height (i.e., potential maximum tree height on that site) has often been used as an approximation of the width of the zone alongside streams that provides effective shading and inputs (e.g., large woody debris) to the channel (Rhodes et al. 1994), although vegetation further from streams can still, in the proper circumstances, provide some shade. This distance (i.e., potential maximum tree height) is roughly 20 m (66 ft) to as much as 30 m (98 ft) in western Placer County, based on the observed and potential heights of mature Fremont's cottonwoods, valley oaks, and other tree species (Hickman 1993; Stuart and Sawyer 2001).

Recommended Setback Width to Conserve Salmonid Habitat Functions

For the purpose of long-term conservation of salmonid habitat functions, the project team recommends that riparian setbacks include the entire active floodplain, regardless of the current extent of riparian vegetation on that surface, and that an additional 30 m (98 ft) buffer be included within the setback. Conversion of the active floodplain to developed or agricultural land uses would substantially affect the hydrologic and geomorphic processes that sustain salmonid habitat functions. Land adjacent to the active floodplain also may affect shade, inputs of woody debris, and water quality; consequently, the 30 m (98 ft) buffer would reduce the effects of adjacent land uses.

It is important to recognize that riparian setbacks are not sufficient to ensure conservation of salmonid habitat functions. Many effects on salmonid habitat functions result from human alterations that are unrelated to setback width, but that are rather associated with flow alterations, water quality, vegetation management, and land uses within the watershed. Therefore, conservation of salmonid habitat functions requires the implementation of a coordinated set of measures involving land use, flow management, and vegetation management in these watersheds and within these defined setbacks.

Chapter 5
Plant Habitat Functions

Introduction

More than 15 native tree and shrub species occur in the riparian forests, woodlands, and scrublands of the Sacramento Valley and adjacent foothills (Conard et al. 1980). These species are all deciduous, and all require high or very high levels of water availability. They differ in their dispersal mechanisms, seed size, shade tolerance, size, growth rates, and longevity (Table 5-1). These attributes, in concert with site conditions and flow and disturbance regimes, determine the species composition and structure of riparian vegetation.

In the Sacramento Valley, early successional vegetation typically is dominated by Fremont's cottonwood (*Populus fremonti*) and willow species (*Salix* spp.). Both taxa produce large numbers of widely dispersed seeds and are rapidly growing, shade intolerant, and relatively short-lived (Sudworth 1908; Strahan 1984; Burns and Honkala 1990). Shrubby thickets of these species can reach heights of 3–12 m (10–40 ft) over a period of 10–20 years. Other species, such as Oregon ash (*Fraxinus latifolia*) and valley oak (*Quercus lobata*), establish either concurrently with or subsequent to the willows and cottonwood and grow more slowly, but they are more tolerant of shade and are longer lived (Burns and Honkala 1990; Tu 2000). In the absence of frequent disturbance, individuals of these species enter the canopy, particularly after 50 years since stand initiation, as mortality of willows and cottonwoods create openings in the forest canopy. Conversely, frequent disturbance prevents the transition to mature mixed riparian or valley oak forests. Currently, in western Placer County, oak species are abundant in the riparian vegetation, white alder (*Alnus rhombifolia*) is widespread, and cottonwoods and willows are less abundant than along many other Central Valley rivers and streams (Appendix A; Placer County 2002).

Human alterations of riparian areas change site conditions, including flow and disturbance regimes, and consequently affect the dispersal, establishment, growth, reproduction, and mortality of riparian species. These changes alter the species composition and structure of riparian vegetation, thereby modifying habitat for aquatic fish and terrestrial wildlife habitat, as well as biogeochemical functions.

Effects of Human Alterations on Life Cycle of Riparian Species

Effects on Dispersal

Air, water and animals disperse riparian plant species. However, flow regime strongly affects the dispersal of all plant species. Surfaces that remain submerged throughout the period of seed release are largely inaccessible to most dispersing seed, and surfaces that remain above water during this period are inaccessible to water-dispersed seed. Seeds are commonly dispersed through the air or by floating on water; large numbers of seeds wash onto shorelines and bars as water levels recede. The river stage during the dispersal period must be at a level high enough to distribute seeds to a surface where scouring by subsequent flows does not occur, and low enough to prevent desiccation of seedlings once the river stage recedes.

Accordingly, hydrologic or geomorphic alterations affect the dispersal of riparian plant species. Levees and berms isolate surfaces from stream flows and preclude the deposition of water-dispersed seed. Flow alterations modify the river's stage, raising or lowering the elevation at which seeds are deposited. Similarly, incision of the stream channel lowers the river's stage, and thus lowers the elevation at which seeds are deposited. Such incision is widespread in western Placer County (Appendix A; Placer County 2002; ECORP 2003; EDAW 2004; Jones & Stokes 2004 c).

Similarly, conversion of active floodplain to agricultural or developed land uses can isolate seed sources and potentially create barriers to flows or animal movements and thus to seed dispersal. However, the extent of these effects is not well known.

Effects on Establishment

Establishment of riparian plants requires suitable conditions for germination and subsequent growth. Hydrology and hydraulics, soil properties, competing vegetation, disease-causing organisms, herbivorous animals, and vegetation management by humans all affect the transition from seed to established plant.

For successful recruitment, cottonwood and willows are particularly dependent on specific hydrologic events before, during, and immediately following their seed release periods. These shade-intolerant species have very small and short-lived seeds (Table 5-1); accordingly, they require establishment sites that are largely free of competition from existing vegetation. The erosion and deposition of sediment along stream channels and on floodplains creates such surfaces. A moist substrate must be maintained for approximately a week following seed dispersal to allow seeds to germinate (Scott et al. 1999, 2000). Following germination, the river stage must decline gradually to enable seedling

Table 5-1. Selected Attributes of Sacramento Valley and Foothill Riparian Tree Species

Species	Seed Size[a]	Seedling Shade Tolerance[b]	Height[c]	Longevity[d] (years)
Box-elder *Acer negundo*	0.1 g (0.001 oz.)	Tolerant	15-25 m (49-82 ft)	50-100
White Alder *Alnus rhombifolia*	0.001 g (0.0001 oz.)	Intolerant	15-25 m (49-82 ft)	50-100
Oregon ash *Fraxinus latifolia*	0.1 g (0.001 oz.)	Tolerant	10-25 m (33-82 ft)	150-250
Walnut *Juglans hindsii*	10.0 g (0.1oz.)	Intermediate	10-20 m (33-66 ft)	50-150
Sycamore *Platanus racemosa*	0.01 g (0.0001 oz.)	Intolerant	10-30 m (33-98 ft)	150-200
Fremont's cottonwood *Populus fremontii*	0.001 g (0.0001 oz.)	Intolerant	15-30 m (49-98 ft)	50-100
Valley oak *Quercus lobata*	1.0 g (0.1 oz.)	Intermediate	10-35 m (33-115 ft)	300-400
Interior Live-oak *Quercus wislizenii*	1.0 g (0.1 oz.)	Intermediate	5-20 m (16-66 ft)	100-200
Goodding's black willow *Salix gooddingii*	0.0001 g (0.00001 oz.)	Intolerant	10-30 m (33-98 ft)	50-100
Narrow-leaved willow *Salix exigua*	0.0001 g (0.00001 oz.)	Intolerant	5 m (16 ft)	20-30
Red willow *Salix laevigata*	0.0001 g (0.00001 oz.)	Intolerant	10-15 m (33-49 ft)	40-60
Arroyo willow *Salix lasiolepis*	0.0001 g (0.00001 oz.)	Intolerant	5-10 m (16-33 ft)	30-50
Shining willow *Salix lucida*	0.0001 g (0.00001 oz.)	Intolerant	5-10 m (16-33 ft)	30-50

establishment. If the river stage declines too quickly, seedlings are prone to mortality by desiccation. To supply seedlings with adequate water as their roots elongate toward the water table, the decline in river stage should not exceed 2.5-3.8 cm (1–1.5 inches) per day (Mahoney and Rood 1998; Shafroth et al. 1998; Scott et al. 1999, 2000).

After germination, seedlings grow on surfaces ranging from immediately below peak-flow to immediately above low-flow elevations. Most seedlings do not survive their first year on these surfaces. Because high levels of soil moisture within several feet of the surface are required for these seedlings to survive through the first summer, seedlings may desiccate on higher elevation surfaces. Moreover, prolonged inundation during the growing season can kill seedlings (Sprenger et al. 2001). Under unaltered conditions, high summer flows typically do not occur; however, where streams are downstream of dams or are used to convey irrigation waters, high summer flows may frequently occur. Finally, flows during the following winter and spring may inundate all surfaces supporting seedlings; seedlings may be scoured from those surfaces inundated with sufficient depth and velocity of water to mobilize the surface (Friedman and Auble 1999). Such scouring is most likely on lower-elevation surfaces.

Historically, flows suitable for cottonwood and willow establishment did not occur in most years. Historical records and tree-aging studies have shown that in numerous riverine environments in the western United States, the combination of factors leading to a large-scale establishment event typically occurs once every 5–10 years (Stromberg et al. 1991; Scott et al. 1997; Mahoney and Rood 1998). Scott et al. (1997) determined that establishment of cottonwoods on the upper Missouri River in an area with little channel movement was most likely on surfaces inundated by floods with a recurrence interval of more than 9 years. Hughes (1994) concluded that long-term cottonwood establishment was associated with even longer flood return intervals (30–50 years) along some non-meandering rivers.

Because other species of riparian trees and shrubs are characterized by larger seed sizes and greater shade tolerance than willows and cottonwoods (Table 5-1), the establishment of such species is less dependent on stream flows. All riparian plants are affected by water availability and competition from existing vegetation, and are consequently affected to some degree by hydrology and the creation of new surfaces by the erosion and deposition of sediment. Some species, such as Oregon ash and valley oak, are able to establish in the shade of other plants; others, such as elderberry and valley oak, can survive drier conditions than can cottonwoods and willows. Thus, in the absence of suitable conditions for willow and cottonwood establishment, other riparian species establish, but the resulting stands differ from cottonwood and willow–dominated stands in species composition, structure, and wildlife habitat value.

Vegetation management activities also affect the establishment of all riparian species. Such activities entail removal of vegetation by means of grazing, herbicide application, and mechanical operations for rangeland and agricultural management; firewood cutting; and levee, floodway, road, and right-of-way maintenance. (Silviculture is not a widespread practice in the Sacramento Valley and foothill riparian areas.) While vegetation removal kills seedlings, it also removes established plants, creating greater opportunities for establishment in subsequent years.

Vegetation management activities occur in western Placer County and may be detrimentally affecting the regeneration of riparian vegetation. Despite stands having a sparse layer of trees and a narrow width, small saplings (i.e., < 2 m [6.6 ft]), particularly those of cottonwoods or willows, often are rare or absent (Appendix A; Placer County 2002). However, hydrologic alterations also may account for these conditions.

Effects on Growth and Reproduction

Growth and reproduction of riparian plants are affected by changes in resource availability and interactions with other species. The effects of human alterations on reproduction have not been documented, except to the extent that reproduction is dependent on growth, and effects on growth have been documented. Human alterations affect the growth of riparian species through surface water diversions and groundwater removals, nutrient inputs, the introduction of nonnative species, and inundation of riparian habitats by dams and reservoirs.

Beyond providing suitable conditions for establishment, flows must be sufficient to maintain existing riparian vegetation year-round. Cottonwoods and willows, in particular, are very susceptible to drought-induced stress. In California, the lack of summer moisture limits these and other riparian tree species to areas with readily available shallow groundwater. Accordingly, groundwater and flows following seedling establishment must be sufficient to maintain the elevation of the riparian groundwater zone or capillary fringe within 10–20 feet of the surface (Jones & Stokes 2000a). Diversions of surface water and groundwater removals that cause groundwater levels to fall could reduce growth and contribute to mortality (Stromberg and Patten 1992). Human alterations increase nutrient inputs to riparian areas thorough atmospheric deposition of nitrogen; additionally, irrigation and stormwater runoff conveys fertilizers from agricultural and developed lands into riparian areas and stream channels. Though the addition of nutrients tends to increase plant growth and biomass, it also affects the cycling of other elements and does not benefit all species equally (Vitousek et al. 1997). Typically, a few species are able to acquire most of the added nutrients, and consequently to outcompete species they would otherwise have been unable to displace. In grasslands, shrublands, and wetlands, nutrient additions have been found to reduce plant species diversity (Vitousek et al. 1997; Keddy 2000). Effects on woody riparian vegetation are undocumented, but are likely to be similar to those reported for other vegetation types.

A number of nonnative species have been introduced and become abundant in the riparian areas of the Sacramento Valley and adjacent foothills (Hunter et al. 2003). These nonnative species create new competitive interactions, and they alter growth by changing resource availability for native species. For example, several introduced species, including black locust (*Robinia pseudoacacia*) and red sesbania (*Sesbania punicea*), fix nitrogen from the atmosphere into biologically available forms via symbioses with soil microorganisms (Hunter 2000; Hunter and Platenkamp 2003). These introduced species may increase nutrient availability for other species. In contrast, tamarisk (*Tamarix* spp.) may reduce water availability for other species (Sala et al. 1996). Several invasive nonnatives, including red sesbania, Himalayan blackberry (*Rubus discolor*), giant reed (*Arundo donax*), and perennial pepperweed (*Lepidium latifolium*), form dense, monotypic stands that preclude the establishment of native species (Bossard et al. 2000).

In western Placer County, many of these invasives are widespread and abundant. For example, Himalayan blackberry is the most abundant species in the shrub layer along western Placer County's streams, and red sesbania grows widely along Dry Creek (Appendix A; ECORP 2003). This non-native vegetation has displaced native species and altered several riparian functions (e.g., conveyance of floodwaters, nitrogen cycling and wildlife habitat).

Effects on Mortality

The mortality resulting from disturbance is integral to the dynamics of riparian vegetation; it affects the proportions of different successional stages and vegetation types within riparian corridors (Stromberg et al. 1991; Malanson 1993; Johnson 1994; Freidman and Auble 1999; Taylor et al. 1999). Along Sacramento Valley and foothill rivers and streams, trees are killed by a number of mechanisms including scour, undercutting by channel migration, uprooting and inundation by flood flows, drought, fire, windthrow, and the removal of vegetation for agricultural or flood control purposes. These disturbances clear spaces for the establishment of early successional vegetation, such as willow thickets and forests dominated by young Fremont's cottonwoods. They also can remove forest vegetation before growth and succession has resulted in the complex canopy structures of mature forests and later successional stages, such as mixed riparian forests and stands of valley oaks. Thus, disturbance regimes determine the proportions of early and late successional vegetation within riparian landscapes.

To maintain both early successional vegetation and mature forests within a riparian landscape, the rate of disturbance must be sufficient to create space for the establishment of new patches of riparian forest, yet not so frequent that it prevents any forest from reaching maturity. Of course, disturbances are not randomly distributed spatially or by type (Conard et al. 1980; Hunter and Parker 1993; Malanson 1993; Freidman and Auble 1999). Disturbance by scour, channel migration, flood flows, and inundation are more frequent and intense at lower elevations (i.e., nearer the stream channel) than at higher elevations (Conard et al. 1980; Malanson 1993; Mitsch and Gosselink 1993; Freidman and Auble 1999; Keddy 2000). In contrast, along Central Valley riparian systems, disturbance by drought and fire is more frequent and intense at higher elevations further from the channel. Thus, across a single cross-section of a riparian corridor, clear gradients exist in disturbance frequency and magnitude. These disturbance gradients, together with interspecific differences in physiological tolerances and establishment requirements, lead to the well-documented zonation of riparian vegetation (Conard et al. 1980; Warner and Hendrix 1985; Mitsch and Gosselink 1993). Accordingly, the persistence of substantial areas of both early successional and mature vegetation within riparian areas is not dependent upon a specific overall average rate of disturbance; rather, it requires only zones of higher and lower rates of disturbance. The combination of flood flows, an actively meandering river channel, and a range of elevations provide such zonation.

Human alterations not only change mortality rates by directly removing vegetation but also by altering hydrology and geomorphic processes. Dams, levees, and surface water diversions isolate riparian areas from the stream channel and floodflows, and thus from associated disturbances. Similarly, bank protection and channelization reduce mortality that can result from channel migration. In addition, groundwater removals can reduce water availability and exacerbate drought-induced mortality of riparian plants.

In western Placer County, substantial areas of riparian vegetation have been converted to developed and agricultural land-cover (Jones & Stokes 2004a, 2004b). For example, along the major streams of western Placer County, approximately a quarter of the land < 20 m (66 ft) from the centerline of a stream, is in developed or agricultural land-cover (Jones & Stokes 2004a, 2004b). The remaining riparian vegetation frequently consists of a narrow band (< 20 m [66 ft]) with a discontinuous layer of trees (Appendix A).

Relationships Between Effects and Setback Width

Human alterations primarily affect riparian plant habitats by vegetation management (e.g., grazing, removal of vegetation to increase conveyance of floodwaters) or by altering hydrology and geomorphic processes. Vegetation management is not necessarily related to setback width, but alterations of hydrologic and geomorphic processes are related to setback width. Infrastructure and other developed land uses within the active floodplain, as well as associated levees, berms, and bank protection, affect hydrology and geomorphic processes; such uses consequently alter the structure and species composition of riparian vegetation. Thus, riparian setbacks narrower than the active floodplain facilitate much more extensive alteration of riparian vegetation than setbacks that extend beyond the active floodplain.

Recommended Setback Width to Conserve Plant Habitat Functions

For the purpose of long-term conservation of plant habitat functions, the project team recommends that riparian setbacks include the entire active floodplain, regardless of the current extent of riparian vegetation on that surface. The distribution of riparian vegetation is not static within the active floodplain, and the diversity of vegetative structure and species composition is strongly related to the hydrologic and geomorphic processes within the active floodplain. Therefore, conversion of any portion of the active floodplain to developed or agricultural land-cover types would not only affect hydrologic and geomorphic functions but would affect plant habitat functions as well.

It is important to note that many human effects on riparian plant habitat functions are not necessarily reduced by establishing setbacks. These effects include the consequences of hydrologic and geomorphic alterations and of vegetation management. Additional measures are necessary to address these effects.

Chapter 6
Terrestrial Animal Habitat Functions

Introduction

The contribution of riparian habitats to biodiversity greatly exceeds the proportional extent of landscape areas they occupy. Scientific documentation of the importance of these habitats for plants and animals has been published in studies conducted across the continent (Sands 1977, Warner and Hendrix 1984, Naiman et al. 1993, 2000; Crow et al. 2000; Brinson et al. 2002).

In western Placer County, Valley Foothill Riparian Woodlands (riparian woodlands) (Mayer and Laudenslayer 1988) and their associated upland habitats provide food, water; cover and migration and dispersal corridors for a higher diversity of wildlife species than any other habitat. Riparian woodlands may support up to 193 vertebrate species, including 133 breeding species and 60 visitors, in western Placer County (Jones & Stokes 2004a). Some animals reside primarily in riparian woodlands year-round, while others occupy these habitats as part of their breeding home range or territories. Many species visit riparian woodlands seasonally or for short periods (e.g., migrating birds).

A number of special-status animals are known to be associated with riparian woodlands in western Placer County: valley elderberry longhorn beetle, foothill yellow-legged frog, western pond turtle, giant garter snake, double-crested cormorant, great egret (rookery), great blue heron (rookery), black-crowned night-heron (rookery), bald eagle, Swainson's hawk, osprey, white-tailed kite, Cooper's hawk, yellow-billed cuckoo (one historical record), long-eared owl, willow flycatcher, purple martin, yellow warbler, yellow-breasted chat, Modesto song sparrow, river otter, ringtail, and an unknown number of bat species (e.g., Townsend's big-eared bat, long-eared myotis, long-legged myotis, and Yuma myotis).

Riparian-associated species vary considerably in their area requirements; many special-status and declining species have large home ranges, and thus require wide riparian areas to maintain viable populations. The habitat and area requirements of riparian-associated birds, mammals, reptiles, and amphibians in western Placer County are summarized in Table 6-1. This list includes only species that depend on riparian woodlands for successful reproduction and survival. Plant and animal population size is often the best predictor of future extinctions or local extirpations; accordingly, habitat patches should be large enough to maintain viable populations of the most area-sensitive species, including special-status and economically important species (Environmental Law Institute 2003).

The primary goal of this chapter is to examine the possible relationships between terrestrial vertebrate diversity (i.e., species' occurrence and abundance) and the extent, width, and condition of riparian woodlands in western Placer County and nearby foothill counties. For each vertebrate group discussed below, the project team evaluated riparian and upland habitat requirements, patch size requirements (area and width), and effects of human activities on those vertebrate groups. The chapter concludes with a summary of the relationships between the width of riparian setbacks and the effects on wildlife habitat due to human alterations, and setback recommendations for conservation of wildlife habitat functions.

Birds

Habitat Relationships

Riparian habitats have been identified as the most important habitat for landbirds in California (Manley and Davidson 1993, Riparian Habitat Joint Venture 2004). Birds of numerous species are abundant in riparian woodlands of western Placer County. Up to 70 species breed in these habitats; an additional 55 species use them for shelter, foraging, or as migratory stopover areas (Jones & Stokes 2004a). Several riparian-associated birds may be covered under the HCP/NCCP for the Phase I Planning Area: Swainson's hawk, yellow-billed cuckoo (one historical record), yellow warbler, yellow-breasted chat, and Modesto song sparrow. Two potentially covered species (bald eagle and bank swallow) may use these habitats for foraging, shelter, or cover but do not breed there (Jones & Stokes 2004a).

Many species of riparian-associated birds are known to breed in western Placer County. These include Cooper's hawk, red-shouldered hawk, Swainson's hawk, black-chinned hummingbird, downy woodpecker, western wood-pewee, Pacific-slope flycatcher, warbling vireo, tree swallow, house wren, yellow warbler (no recent breeding records), yellow-breasted chat, common yellowthroat, Modesto song sparrow, black-headed grosbeak, blue grosbeak, and American goldfinch (Table 6-1).

Riparian Habitat Requirements

Riparian-associated bird species occupy a wide variety of ecological niches; accordingly, they require a complex vegetative structure for breeding, foraging, and shelter/cover (Riparian Habitat Joint Venture 2004). Riparian woodlands provide many niches for breeding birds because they typically support diverse plant communities, are varied in their vertical and horizontal structures, and

Table 6-1. Habitat and Area Requirements of Riparian-Associated Vertebrates of Western Placer County

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Pacific treefrog* *Hyla regilla*	Most move < 10 m; capable of moving up to 400 m (Schaub and Larsen 1978)	Circles with radii of 50 cm (Whitney 1980)	Breeding, cover, foraging	Breeds in water; takes cover under logs and vegetation. Uses all riparian stages and temporary water sources (Zeiner et al. 1988)	Cover, foraging	Requires upland sites for cover during nonbreeding season, takes cover in moist niches under logs and vegetation (Zeiner et al. 1988)
Common garter snake* *Thammophis sirtalis*	Probable overlap between pairs during the spring-fall activity period (Zeiner et al. 1988)	Not thought to be territorial; they often remain aggregated from fall until spring (Zeiner et al. 1988)	Cover, foraging, breeding	Permanent and semi-permanent water bodies. Seeks cover in holes and small mammal burrows, often basks on flat rocks and rotting logs near cover (Zeiner et al. 1988)	Cover, foraging, but only in cold northern climates	May migrate to inland localities during winter in cold northern climates (Zeiner et al. 1988)
Western terrestrial garter snake* *Thamnophis elegans*	Probable overlap between pairs during the summer activity period (Zeiner et al. 1988)	Not thought to be territorial (Zeiner et al. 1988)	Cover, foraging, breeding	Permanent and semi-permanent water bodies. Seeks cover in holes and small mammal burrows, often basks on flat rocks and rotting logs near cover (Zeiner et al. 1988)	Cover, foraging	In mild climates, mammal burrows and surface objects (rocks and rotting logs) serve as winter refuges (Zeiner et al. 1988)
Giant garter snake* *Thamnophis couchi gigas*	Probable overlap between pairs during summer activity period; may migrate between wetland habitats and upland sites that provide winter hibernacula (Zeiner et al. 1988)	Not thought to be territorial (Zeiner et al. 1988)	Cover, foraging, breeding	Highly aquatic; seeks cover in holes and small mammal burrows, crevices, and surface objects. Often basks in streamside vegetation. Rocks and rotting logs serve as winter refuges	Cover, foraging	In mild climates, mammal burrows and surface objects (rocks and rotting logs) serve as winter refuges (Zeiner et al. 1988)
Cooper's hawk *Accipiter cooperii*	*Michigan* – four home ranges averaged 311 ha, range 96–401 ha; 17 others averaged 207 ha, range 18–531 ha *Wyoming* – One home range of 205 ha (Craighead and Craighead 1956).	Males defend ~100 m around potential nest sites prior to pair formation (Brown and Amadon 1968). *Oregon* – nests were 3.2–4.2 km apart (Jackman and Scott 1975). Elsewhere, nests were 1.6–2.4 km apart (Meng 1951, Brown and Amadon 1968). *California* – In oak stands, mean distance between nests was 2.6 km (Zeiner et al. 1990a)	Breeding, foraging, perching	Needs dense stands of live oak, riparian deciduous, coniferous, or other forest habitats near water; nests in crotches 3–23 m high (Zeiner et al. 1990a)	Breeding, foraging, perching	Hunts in patchy wooded areas and edges; needs snags or dense tree stands for perching and waiting for prey (Beebe 1974). Dense stands with moderate crown-depths used for nesting (Zeiner et al. 1990a)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Red-shouldered hawk* *Buteo lineatus*	*Michigan* – averaged 63 ha, range 19–384 ha (Craighead and Craighead 1956)	Same as home range	Breeding, perching, foraging	Extensive stands of forest with tall trees and variable amounts of understory required for breeding (Crocoll 1994)	Cover, foraging	Does not require upland sites, but will use them for foraging and roosting; mostly forages in oak woodlands and adjacent annual grasslands (Zeiner et al. 1990a)
Swainson's hawk+ *Buteo swainsoni*	*Wyoming* – five pairs averaged 2.5 km^2 (Craighead and Craighead 1956) *California* – 12 pairs, 2,760–2,553 ha (Estep 1989); 5 pairs ranged 4,038–2,663 ha (Babcock 1995) *Washington* – eight pairs, 621–214 ha (Fitzner 1978); five pairs, 886–243 ha (Bechard 1982) *Colorado* – eight pairs, 2,429–1,050 ha (Andersen 1995) Nest sites in riparian forest close to alfalfa or recently harvested row crops corresponded to smaller home ranges (Estep 1989)	No specific information on territory size (England et al. 1997); three territories were found within a 1.1-km length of riparian forest in the Central Valley (Bloom 1980)	Breeding and perching	Requires large trees to support nests, but will nest in open habitats with scattered trees and small groves near water (Bloom 1980); nests 1.3–30 m above ground (Zeiner et al. 1990a)	Breeding, foraging, perching	Not an obligate riparian species; needs proximity to good foraging habitat such as grassland, pasture, or grainfields; primarily needs large trees for nesting (Woodbridge 1998; Zeiner et al. 1990a); may nest in open grassland or cropland habitats with scattered trees (England et al. 1997)
Yellow-billed cuckoo+ *Coccyzus americanus*	Large home ranges averaging 17 ha (Laymon and Halterman 1987)	10 ha is an appropriate minimum patch size (Halterman pers. comm.)	Nesting, foraging, perching	Optimal stands defined as more than 80 ha in extent and more than 600 m wide, marginal stands as 20–40 ha and 100–200 m wide, and unsuitable stands as less than 15 ha and less than 100 m wide (Laymon and Halterman 1989)	Foraging	May forage in uplands adjacent to riparian woodlands, especially early successional stands of cottonwoods and willows (Laymon and Halterman 1989). 10 ha is an appropriate minimum patch size for this species (Halterman pers. comm.)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Black-chinned hummingbird+ *Archilochus alexandri*	No data	*S. California* – male breeding territory averaged 0.1 ha (Stiles 1973); 41–130 nests per 40 ha (Pitelka 1951) *Arizona* – eight nests per 40 ha in oak woodland; 21 per 40 ha in oak juniper woodland (Balda 1970)	Nesting, foraging, perching	Sparse to open riparian woodland preferred for breeding; uses trees and shrubs for cover; places open cup nest in understory (0.9–9.1 m above ground) near water source (Grinnell and Miller 1944; Zeiner et al. 1990a)	Occasional breeding, mostly foraging	Woodland and scrub habitats adjacent to riparian areas used for feeding during breeding season. Occasionally nests in orchards (Zeiner et al. 1990a)
Downy woodpecker* *Picoides pubescens*	Territory and home range are the same (Zeiner et al. 1990a)	*Ontario* – two breeding territories of 2.0 and 3.2 ha (Lawrence 1967)	Breeding, foraging, cover	Associated with riparian deciduous softwoods; uses tree and shrub foliage for cover; requires abundant snags and tree/shrub, tree/herbaceous, and shrub/herbaceous ecotones (Zeiner et al. 1990a). Excavates nest cavity in snag (preferably aspen) or dead branch 1.3–15 m high (Bent 1939; Lawrence 1967)	Foraging, cover	Frequents hardwoods, conifer habitats, and orchards adjacent to riparian areas (Zeiner et al. 1990a)
Western wood-pewee+ *Contopus sordidulus*	No information found, but probably equal to territory. Density estimates range from 1–10 pairs per 40 ha in Colorado aspen-conifer habitat (Beaver and Baldwin 1975) to 18–33 pairs per 40 ha in Sacramento Valley riparian habitats (Gaines 1974)	*Colorado* – territory averaged 1.2–1.6 ha over 3 yrs (Eckhardt 1976). Territory size probably varies widely depending on habitat and foraging conditions (Zeiner et al. 1990a)	Breeding, perching, foraging	Uses trees of almost any size, especially with dead lower branches, for nesting, singing, and foraging perches. Places open cup nest 4–25 m above ground. Nests in woodlands edging riparian areas and in valley foothill riparian habitats (Zeiner et al. 1990a)	Breeding, roosting, foraging	Nests in open woodlands with sparse to moderate canopy, most commonly in ponderosa pine, montane hardwood-conifer, mixed conifer, Jeffrey pine, lodgepole pine, eastside pine, red fir, and aspen (Grinnell and Miller 1944; Garrett and Dunn 1981; Zeiner et al. 1990a)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Willow flycatcher+ *Empidonax traillii*	In breeding season, probably equal to territory. *Washington* – 9.2 pairs per 40 ha in scrub habitat (King 1955) *Michigan* – 60.7 individuals per 40 ha in scrub habitat (Berger 1957)	*California* - six paired males ranged 0.09–0.38 ha and averaged 0.18 ha in Fresno County (KRCD 1985); 22 territories ranged 0.06–0.89 ha and averaged 0.34 ha in Sierra County (Sanders and Flett 1989); monogamous males averaged 0.6 ha (SD = 0.35, n = 24, range 0.1–1.3) and polygynous males averaged 1.1 ha (SD = 0.68, n = 24, range 0.2–2.8) at the South Fork Kern River (Whitfield and Strong 1995; Whitfield and Enos 1996; Whitfield et al. 1997). *Arizona* – range 0.06–1.5 ha (Sogge et al. 1997). *Michigan* – avg. size was 0.7 ha (Walkinshaw 1966)	Nesting, foraging, perching	Broad river valleys or moist mountain meadows where lush thickets of dense willows, alders, and cottonwoods edge on wet meadows, ponds, or backwaters (Zeiner et al. 1990a; Serena 1982; Harris et al. 1988; Whitfield et al. 1997; Sanders and Flett 1989). In mountain meadows prefers willow thickets interspersed with open space; in lowland riverine habitats prefers contiguous willow thickets (Harris 1991). Does not occur in areas of dense tree cover (King 1955; Walkinshaw 1966)	Migration	May migrate into higher elevations after breeding and during fall migration (Grinnell and Miller 1944). No specific data un upland habitat use
Pacific-slope flycatcher+ *Empidonax difficilis*	*Colorado* – 5–28 individuals/40 ha in conifer forest (Beaver and Baldwin 1975) *California* – 11 males/40 ha in broadleaf evergreen forest in Alameda County (Cogswell 1973), 35 males/40 ha in buckeye/California bay mixed forest in Marin County (Stewart 1973)	No data	Breeding, foraging, perching	Breeds in shady alder and willow thickets and similar riparian growth in oak woodlands, redwood, and ponderosa pine forests (Zeiner et al. 1990a)	Foraging, perching, migration	Frequents shaded woodlands and forests with dense canopy adjacent to riparian habitat during breeding season. Occurs in more open habitats in migration (Zeiner et al. 1990a)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Warbling vireo+ *Vireo gilvus*	*Idaho* – one pair had a 37-m radius around the nest (Rust 1920); five pairs/40 ha in a cut-over Douglas-fir forest (Johnston 1949) *Arizona* – 42 pairs/40 ha in fir-pine-aspen forest (Haldeman et al. 1973) *California* – 40 pairs/40 ha in an oak/bay mixed forest (Stewart 1973); 21 pairs/40 ha in a lodgepole-aspen forest (Winkler and Dana 1977); eight pairs/40 ha in a broadleaf evergreen forest (Cogswell 1973)	*California* – nine pairs in coastal riparian forest averaged 1.45 ha; 19 territories in eastern California averaged 1.2 ha (Gardali and Ballard 2000) *Arizona* – 2 pairs were both 1.2 ha (Barlow 1977). *Illinois* – One pair was ~1.2 ha (Gardali 2003). *Ontario* – Three pairs ~1.2-1.5 ha (Gardali 2003). *Alberta* – Two pairs were both 1.5 ha (Gardali 2003)	Breeding, foraging, perching	Nests in mature mixed deciduous woodlands along riparian corridors (Gardali 1998). Likes edges and openings, large trees, and semi-open canopy (James 1971; MacKenzie et al. 1982; Marzluff and Lyon 1983; Verner and Boss 1980) According to Grinnell and Miller (1944), may be more attracted to riparian trees than to moisture	Occasional breeding, perching, and migration	Commonly uses deciduous trees, shrubs and conifers for cover. Occasionally breeds in conifer habitats and forest interiors near edges and openings (Zeiner et al. 1990a; Gardali 1998). Also occurs in desert riparian, orchards, vineyards, and urban habitats during migration (Zeiner et al. 1990a; Gardali 1998)
Tree swallow+ *Tachycineta bicolor*	Kuerzi (1941) stated home range is "large"	*California* – 4–18 pairs/40 ha in riparian habitat (N = 3) and 2–10 pairs/40 ha in mixed conifer forest (N = 4) in the Sierra Nevada (Raphael and White 1978)	Breeding, foraging, cover	Requires trees and snags with cavities in forest and riparian woodland for nesting and cover (Zeiner et al. 1990a)	Breeding, foraging, perching, migration	Will nest in lodgepole pine belts. Common to occasional transient throughout the state in virtually all non-desert habitats (Zeiner et al. 1990a)
House wren* *Troglodytes aedon*	No data	*Oregon* – 14 breeding territories averaged 0.9 ha, range 0.5–1.8 ha (Kroodsma 1973) *Ohio* – 178 breeding territories averaged 0.4 ha, range 0.03–1.5 ha (Kendeigh 1941b)	Breeding, foraging, cover	Brushy understory beneath oaks and other riparian deciduous trees. Requires cavities in trees and snags with thickets nearby for foraging (Zeiner et al. 1990a)	Dispersal	Moves upslope after breeding in the Cascades and Sierra Nevada (Zeiner et al. 1990a)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Yellow warbler+ *Dendroica petechia*	*New York* – less than 0.2 ha (Ficken and Ficken 1966) *Iowa* – 0.16 ha (Kendeigh 1941a)	*California* – 0.40–.74/ha (mean 1.64 SE + 0.12) in early successional habitats of eastern Sierra Nevada (PRBO unpublished data) *Iowa* – 0.16/ha in prairie community *Minnesota* – range 0.03–1.62 ha (Beer et al. 1956) *Michigan* – polygynous male territories (0.78 ha) significantly larger than those of monogamous males (0.21 $\pm$ 0.05 ha) (DellaSala 1986) Territory size variable depending on availability of foraging area (Kendeigh 1941)	Breeding, foraging, perching	Nests in early successional riparian habitat or remnant or regenerating canopy with good shrub cover. Prefers deciduous trees such as willows, alders, sycamore, maples, and cottonwoods; in the eastern Sierra breeds locally in wild rose and more xeric plant species and habitats (Heath 1998)	Breeding, foraging, perching	Breeds in montane shrubs in open conifer forests (Gaines 1977). In migration, visits woodland, forest, and shrub habitats (Zeiner et al. 1990a). Kendeigh observed individuals regularly moving up to 488 m to a willow-marsh edge to feed. (Zeiner et al. 1990a). *D.p. brewsteri* was found to breed in locations away from water in the Modoc Bioregion (Grinnell et al. 1930).
Common yellowthroat *, + *Geothlypis trichas*	*Michigan* – 1.4 ha for polygynous male; 10 pairs ranged 0.3–0.7 ha in marsh and riparian habitats (Stewart 1953) *New York* – seven pairs spaced uniformly over 2.0–2.4 ha in a brush field (Kendeigh 1945)	*California* – 1.04 territories/ha in Marin County (Evens et al. 1997); spacing of 0.2–2.0 ha reported by Foster (1977) in the SF Bay *Michigan* – 0.3–0.7 ha (Stewart 1953) *New York* – spacing of 2.0–2.4 ha	Breeding, foraging, perching	Needs tall, emergent herbaceous wetlands and low, dense vegetation near water (Timossi 1990; Zeiner et al. 1990)	Occasional breeding, migration	Occasionally breeds in dense shrubs and annual/perennial grasslands (Garrett and Dunn 1981; Zeiner et al. 1990). Brushy habitats used in migration (Zeiner et al. 1990a)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Yellow-breasted chat + *Icteria virens*	*California* – 10pairs/40 ha reported in the Sacramento Valley (Gaines 1974)	*Indiana* – avg. 1.24 ha (range 1.12–1.58 ha). Males that arrived early established large territories that shrunk as more males arrived; males expanded their territories if neighboring territories were abandoned (Thompson and Nolan 1973)	Breeding, foraging, perching	Requires dense riparian thickets of willows, vine tangles, and dense brush associated with streams, swampy ground, and borders of small ponds (Small 1994). Uses taller trees as song perches (Dunn and Garrett 1997). Nest substrate in California consists of blackberry, wild rose, and pipevine (Ricketts and Kus 2000; Burnett and DeStaebler 2002)	Dispersal	May wander upslope post-breeding (Gaines 1977)
Song sparrow * *Melospiza melodia*	*New York* – 0.6 ha (Butts 1927) *Kansas* – 3.6 ha winter home range; 29 home ranges averaged ~2.8 ha (Fitch 1958) *British Columbia* – averaged 0.05 ha in an island population (Tompa 1962)	*California* Modoc Bioregion: 1.94 territories/ha (n=14) (King and King 2000). Sierra Bioregion: 0.2–1.2 territories per creek km (Heath and Ballard 1999) Bay/Delta Bioregion: 4.4–8.1 territories/ha (Gardali et al. 1998) *British Columbia* – 1.7–5.6 pairs/ha (Rogers et al. 1997)	Breeding, foraging, perching	Breeds in early successional riparian habitat, emergent wetlands, and coastal scrub (Burridge 1995; Roberson and Tenney 1993). Requires water, dense vegetation, light, and exposed ground for foraging (Marshall 1948) Abundance is negatively correlated with tree cover and closed canopy cover ($p<0.05$) (Holmes et al. 1999)	Breeding, foraging, perching	Regularly breeds in coastal scrub habitat, which provides enough water in the form of fog (Humple and Geupel 2004). In winter may be found far from water, in open habitats with thickets of shrubs or tall herbs. Usually avoids densely wooded habitats, except along forest edges (Zeiner et al. 1990a)
Black-headed grosbeak+ *Pheucticus melanocephalus*	*California* – 31–66 singing males/40 ha (Gaines 1974)	*New Mexico* – 0.79 ha (n=28, range=0.43-1.63ha) (Hill 1988; Hill 1995) *Utah* – 2.7 ha (n=12, range=1.9–3.0 ha) (Ritchisson 1983) No information available for California	Breeding, foraging, perching	Requires vegetation density and vertical complexity (Hill 1988); trees and shrubs as low as 1 m to support nests (Zeiner et al. 1990a); favors cottonwood/ willow associations (Grinnell and Miller 1944) with a primary and secondary canopy, variety in shrub height, and patches of herbaceous cover (Gaines 1977)	Occasional nesting, foraging, perching	Sometimes nests in open woodlands, orchards, or edges of dense woodlands (Zeiner et al. 1990a, Lynes 1998)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Blue grosbeak+ *Guiraca caerulea*	No data	*South Carolina* – 5.2–6.12 ha (Odum and Kuensler 1955) *Georgia* – 1.2 ha in tung-oil groves (White 1998)	Breeding, foraging, perching	Prefers riparian edges, forest/field edges, or forest/gravel-bar interfaces (Gaines 1974) with herbaceous annuals and young, shrubby willows/cottonwoods (Grinnell and Miller 1944). Prefers upright growing herbs for nest placement, and tall shrubs and trees for singing perches and shade for nest sites (White 1998)	Foraging, dispersal, migration	Forages in openings, grasslands, and croplands adjacent to riparian areas. Not limited to riparian habitats post breeding or in migration (Zeiner et al. 1990a)
American goldfinch* *Carduelis tristis*	*Michigan* – nesters fed up to 274 m from nest (Nickell 1951) and at least 0.8 km from nest (Coutlee 1967); 53–205 pairs/40 ha (Berger 1957) *California* – 10–33 males/40 ha (Gaines 1974)	*Michigan* – males defended 30 m around nest and built nests at least 35 m apart (Coutlee 1967) *Wisconsin* – 9.1–27 m around nest in marshland (Stokes 1950)	Breeding, foraging, perching	Nests in riparian deciduous woodland near feeding areas in brushy or herbaceous habitats (Coutlee 1967). Must be near water and may require trees for roosting (Zeiner et al. 1990a). Uses willow, cottonwood, or other riparian deciduous tree as nesting substrate (Grinnell and Miller 1944)	Breeding, foraging, perching	Will move upslope after breeding (Zeiner et al. 1990a). May nest in oaks, orchards, other upland shrubs, or thistles (Grinnell and Miller 1944)
Ornate shrew* *Sorex ornatus*	Occurrence and abundance of shrews varied significantly between sites and years but the size of the landscape or the study site had no effect on their abundance; peak densities usually occurred during the spring (Laakkonen et al. 2001).	No data found.	Breeding, foraging, cover	Optimum habitats are foothill and montane riparian (Zeiner et al. 1990b). The amount of urban edge had no significant effect on the captures of shrews but increased edge allows invasion of the Argentine ants, which had a highly significant negative impact on shrew abundance (Laakkonen et al. 2001)	Breeding, foraging, cover	Occurs in a variety of woodland, scrub, and grassland habitats and occupies dry, upland sites more commonly than most other shrews (Zeiner et al. 1990b)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Yuma myotis *Myotis yumanensis*	Radio telemetry studies showed that direct line distances between capture sites and first day roosts averaged 2,007 m, and 1,130 m for roost sites on consecutive days (Evelyn et al. 2004)	Territoriality has not been reported; probably not territorial at foraging or roosting sites; roosts in large groups numbering from about 200 to thousands of individuals (Zeiner et al. 1990b)	Breeding, foraging, cover	Usually forages over water, and seems to be more closely associated with water than any other North American bat species (Barbour and Davis 1969). Riparian habitats offer optimal habitats for this species since they provide suitable roosting and breeding habitat a nearby source of water for foraging (Zeiner et al. 1990b). Large maternity colonies may be found in buildings, caves, under bridges (Zeiner et al. 1990b), and in large trees (Evelyn et al. 2004). Prefers to roost in large trees (mean diameter 115 cm) that provide suitable cracks, crevices, and cavities; roost sites are usually near water (mean 133 m from water) (Evelyn et al. 2004)	Breeding, foraging, cover	Found in a wide variety of habitats from the coast to mid-elevations, and preferred habitats include open forests and woodlands near sources of water for foraging (Zeiner et al. 1990b).
Beaver* *Castor canadensis*	*Canada*—colonies had home range of 0.8 km radius from lodge, or about 201 ha (Aleksiuk 1968) *California*—colony home range was about 15 ha (Light 1969)	*Canada*--territory boundaries maintained by scent mounds, averaged 0.4 km radius, or about 50 ha (Aleksiuk 1968); colonies closer together formed more scent mounds than did more isolated colonies (Butler and Butler 1979)	Breeding, foraging, cover	In winter forages almost entirely on the bark and cambium of riparian trees including aspen, willow, alder, and cottonwood; forages mostly on streambanks, felling trees and harvesting branches for winter food. Builds lodges out of branches and mud, usually on streamside banks or on islands. Takes cover in lodge or by diving in water; makes dams to form deeper ponds for foraging and taking cover (Zeiner et al. 1990b)	Foraging	Forages us to 200 m from water; cuts a variety of trees but tends to take smaller trees far from water (Jenkins 1980)

Table 6-1. Continued

			Riparian		Upland	
Species	Home Range Size	Territory Size	Habitat Use	Habitat Requirements	Habitat Use	Habitat Requirements
Ringtail* *Bassariscus astutus*	No information available	*California* – estimated to vary from 44–515 ha (Grinnell et al. 1937) *Texas* – average size estimated at 20–43 ha (Toweill and Teer 1981)	Breeding, foraging, cover	Breeds and takes cover in hollow logs, trees, and cavities in talus and other rocky areas, usually near water (Zeiner et al. 1990b). Primarily carnivorous; prefers rodents and rabbits. Also consumes birds and eggs, reptiles, invertebrates, fruits, nuts, and some carrion (Trapp 1978)	Foraging	Forages primarily in riverine and riparian areas, but may also use nearby uplands if suitable prey is available (Zeiner et al. 1990b)
Raccoon* *Procyon lotor*	*Michigan*—home ranges of males averaged 204 ha and varied from 18 to 814 ha (Stuewer 1943) *North Dakota*—home ranges of males varied from 396 ha to 1,468 ha, and females varied from 532 to 743 ha for females (Fritzell 1977)	Radiotelemetry studies suggest that males may be territorial, but females probably are not; no information on territory size available (Zeiner et al. 1990b)	Breeding, foraging, cover	Found in greatest abundance in low and mid-elevation riparian habitats; takes cover and breeds in tree cavities, snags, and downed logs. Usually forages for both animal and plant material in shallow water (Zeiner et al. 1990b)	Breeding, foraging, cover	Frequents a high diversity of habitats including upland areas such as forested, shrub, and herbaceous areas; may use rocky areas for dens or cover; a source of water is required for foraging and washing (Zeiner et al. 1990b)
River otter* *Lutra canadensis*	Home ranges may extend an average of 24 km along rivers and streams (Haley 1975); travel distance is highly variable and depends on food supplies and habitat quality; may travel 80 to 96 km along streams during a year (Liers 1951)	Males known to establish scent posts using urine, feces, and musk but no information on territory size available ((Zeiner et al. 1990b)	Breeding, foraging, cover	Uncommon residents of riparian habitats and associated streams and rivers; takes cover and nests in burrows and cavities in river banks; also uses hollow logs, stumps, snags, abandoned beaver lodges, and natural cavities in riparian habitats (Zeiner et al. 1990b)	Foraging	Seldom moves away from water but may pursue prey short distances from water courses into upland habitats (Sheldon and Toll 1964)

* Resident (at least partially) in riparian habitats of western Placer County.

+ Neotropical migrant species that breed in riparian habitats of western Placer County or in nearby counties.

provide a source of surface water (MacArthur 1964; James 1971; Rice et al. 1983, 1984; Brinson et al. 2002). Many riparian areas offer a range of successional habitats due to the dynamic nature of their hydrology. Riparian woodlands are also critical to a diversity of migratory birds (e.g., raptors, flycatchers, vireos, warblers, tanagers, sparrows, and grosbeaks) that depend on trees and shrubs near streams for shelter/cover and for the rich food supplies (e.g., insects, seeds, and fruits) associated with these areas (Jones & Stokes 2004a). Moreover, riparian areas can also provide perching, nesting, and foraging habitat, as well as water, for bird species that primarily nest in upland areas (Heath and Ballard 2003).

Because habitat heterogeneity promotes animal diversity, the highest bird abundance and species richness are usually found in riparian woodlands with a variety of different successional stages (i.e., young and old trees) and a lush understory of shrubs and/or herbaceous plants. Many breeding bird species prefer specific successional stages of riparian woodlands. For example, song sparrows, blue grosbeaks, yellow-breasted chats, yellow warblers, and common yellowthroats are often most abundant in early successional habitats (e.g., stands approximately 2 to 4 m [6.5 to 13 ft] tall) with dense vegetation near the ground. Other species, such as Cooper's hawks, red-shouldered hawks, yellow-billed cuckoos, tree swallows, and black-headed grosbeaks, prefer late-successional stands with taller trees and snags (e.g., more than 10 m [33 ft] tall) that are required for nesting substrates and/or song or foraging perches. Some bird species (most woodpeckers, owls, and some swallows and flycatchers) require large snags for nesting (Zeiner et al. 1990a; Riparian Habitat Joint Venture 2004).

Riparian areas also provide essential habitat for migratory birds and wintering species. For example, willow flycatchers (state listed as endangered) require these habitats during spring and fall migration, but they do not remain to nest in western Placer County (Table 6-1). Many other species of Neotropical birds such as vireos, warblers, thrushes, and grosbeaks also depend on riparian habitats for cover and foraging during migration (Riparian Habitat Joint Venture 2004).

Upland Habitat Requirements

Upland habitats provide migratory stopover grounds, foraging habitat, and dispersal corridors for non-breeding adults and juveniles of many riparian-associated species. For this reason, the adjacent land cover is a strong determinant of the species composition of a specific habitat area (Appendices A and B). Yellow-billed cuckoos, yellow warblers, common yellowthroats, and song sparrows are among the many riparian-associated species that may forage in upland habitats adjacent to riparian nesting sites (Zeiner et al. 1990a). Upland areas serve both as refugia during floods and as supplemental or primary foraging areas at other times of year. Riparian areas also can support primarily upland nesting bird species for perching, nesting, foraging, and water (Heath and Ballard 2003). Uplands can also be important for juvenile dispersal. For example, in coastal California, juvenile Swainson's thrushes use uplands regularly during the post-fledgling period (PRBO unpublished data). Swainson's hawk is an example of a species that frequently nests in riparian woodlands in the Central Valley but forages in upland habitats consisting of large, flat, open, undeveloped landscapes with suitable grassland or agricultural foraging habitat. Swainson's hawks usually nest in large native trees such as valley oaks, cottonwoods, and willows, although nonnative trees, such as eucalyptus, are also used (England et al. 1997). Other primarily riparian-associated birds that often forage in adjacent, upland habitats include Cooper's hawks, red-shouldered hawks, tree swallows, blue grosbeaks, and American goldfinches (Table 6-1).

Patch Size and Riparian Width Requirements

Numerous studies in North America have demonstrated that breeding bird species richness and abundance are positively correlated with riparian width and patch size—at least for riparian-associated and forest interior species. The following studies from California, other states, and Canada provide examples of the relationships between riparian width and patch size and bird species richness and abundance.

California

- In the California Central Valley, riparian bird species richness increased with the width of the riparian zone (Stralberg et al. 2004 [Appendix B of this report]). Species richness was positively associated with riparian width along mainstem rivers, but not along smaller, tributary streams, with a significant increase in species richness occurring beyond 100 m (Appendix B).
- Also in the Central Valley, the occurrence of three riparian-associated species (i.e., black-headed grosbeak, common yellowthroat, and yellow warbler) also was positively associated with riparian zone width (Appendix B). Black-headed grosbeak presence was positively associated with riparian width at mainstem, but not tributary sites, while the reverse was true for the yellow warbler and common yellowthroat. For all three species, significant increases in abundance occurred when the riparian zone was greater than 100 m in width (Appendix B).
- In the San Francisco Bay Area, bird species richness and density decreased as the number of artificial structures (i.e., bridges) increased and as the volume of native vegetation decreased due to urbanization (Rottenborn 1999).
- In coastal Marin County, the abundance of warbling vireos, Swainson's thrushes, and common yellowthroats increased with the width of the riparian corridor. There was no association between riparian width and bird species diversity or richness (Holmes et al. 1999).
- In the eastern Sierra, bird species diversity was positively correlated with riparian width and tree species diversity (Heath and Ballard 2003).

- In California, Song Sparrows and Spotted Towhees have been observed in strips as narrow as 1 m, and other species have been observed in strips 10 m wide (Soulé 1988, PRBO unpubl. data).

Other States

- Along Oregon's headwater streams, riparian buffers are likely to provide the most benefit to riparian- and forest-associated birds if they are more than 40 m (131 ft) wide (Hagar 1999).
- In eastern Oregon, total abundance of riparian birds was greater in continuous shrub associations than in discontinuous shrub associations (Sanders and Edge 1998).
- In Texas, bird abundance was positively correlated to forest width, and streamside forests more than 50 m (164 ft) wide supported the greatest number of total species; area-sensitive bird species increased in abundance in these forests as widths increased from 25 to 100 m (82 to 328 ft); and narrow riparian strips were usually inhabited only by species associated with early successional vegetation and habitat edges (Dickson et al. 1995).
- In South Carolina, species richness of all birds (including Neotropical migrant birds) increased with the width of riparian stands. Narrow riparian strips (less than 50 m [164 ft] wide) supported an abundant and diverse avifauna, but conservation of wide strips (more than 500 m [1,640 ft] wide) was required to support the complete avian community characteristic of that region (Kilgo et al. 1998).
- In Iowa, bird species richness increased with the width of wooded riparian habitats (from 10 to 200 m [33 to 656 ft]), and area-sensitive species were only present on the widest plots (Stauffer and Best 1980).
- In Pennsylvania, most area-sensitive bird species did not occur in riparian zones less than 25 m (82 ft) wide. However, the presence of very narrow (e.g., 2 m [7 ft]) bands of woody vegetation along streams was found to be important for some bird species in disturbed areas (Croonquist and Brooks 1993).
- In Maryland and Delaware, the species richness of area-sensitive riparian birds increased in width zones between 25 m (82 ft) and 100 m (328 ft), and several Neotropical migrant species were only found in riparian forests more than 100 m (328 ft) wide (Keller et al. 1993).

Canada

- In Alberta, forest-dependent bird species declined as buffer width narrowed from 200 m (656 ft) to less than 100 m (328 ft) (Hannon et al. 2002).
- In Quebec, riparian strips less than 40 m (131 ft) wide had the highest mean bird densities (Darveau et al. 1995).

- In Newfoundland, total numbers of interior forest birds may increase in wider buffers, but these species were rare even in the widest strips sampled (40–50 m [131–164 ft]) (Whitaker and Montevecchi 1999).

Overall, the species richness (i.e., total number of species) and abundance (i.e., number of individuals within a species) of riparian-associated species are highest in wide and continuous riparian corridors; this pattern is especially true for area-sensitive species. The effect of riparian width depends on each species' needs, the riparian habitat type and its historic conditions, and attributes of the surrounding landscape. Fragmentation of riparian woodlands could be especially detrimental to nonmigratory species such as song sparrows and spotted towhees that generally do not disperse over large distances. Even thin strips of connecting habitat, while usually not suitable for nesting, can benefit sedentary species that will not disperse through open habitats (e.g., grasslands or barren areas) (Croonquist and Brooks 1993).

Patch size requirements for each species depend on territory and home range sizes and relative sensitivity to fragmentation (Tewksbury et al. 1998; Riparian Habitat Joint Venture 2004). In planning the conservation of an assemblage of species, those species with greatest sensitivity to habitat fragmentation should be used to set patch size requirements (Tewksbury et al. 1998). In western Placer County, some of the most area-sensitive bird species are raptors (home ranges often larger than 100 ha [247 ac]), yellow-billed cuckoos (home ranges larger than 10 ha [25 ac]), downy woodpeckers, and yellow-breasted chats (home ranges greater than 1 ha [2.5 ac]). These species require relatively large areas of riparian habitat to breed and forage successfully (Table 6-1).

Yellow-billed cuckoo is an example of a species that requires large tracts of late-successional riparian forest for breeding habitat. This species was a rare historical visitor to western Placer County, but it has not been recorded there in many decades (Jones & Stokes 2004a). However, yellow-billed cuckoos are regular breeders in wide riparian forests along the Sutter Bypass, about 12 km (7.5 mi) from the Placer and Sutter county line. Using radio-telemetry, Laymon and Halterman (1987) determined that yellow-billed cuckoos have large home ranges, averaging 17 ha (42 ac). Optimal stands were defined as more than 80 ha (198 ac) in extent and wider than 600 m (1,970 ft), marginal stands as 20–40 ha (49–99 ac) in extent and 100–200 m (328–656 ft) wide, and unsuitable stands as less than 15 ha (37 ac) in extent and less than 100 m (328 ft) wide Laymon and Halterman (1989).

Effects of Human Alterations on Riparian Birds

Habitat Loss and Degradation

In the western United States, approximately 95% of riparian habitats have been lost or degraded due to human activities during the past 100 years (Smith 1977, Ohmart 1994). These habitats represent less than 1% of most western landscapes, yet they provide breeding habitat for more than 50% of bird species in this region (Ohmart and Anderson 1982; Rice et al. 1983; Ohmart 1994; Tewksbury et al. 2002). Throughout the Central Valley and Sierra Nevada foothills, riparian habitats have been reduced to a small fraction of their original extent (Hunter et al. 1997, Riparian Habitat Joint Venture 2004), and those habitats that remain have been fragmented and degraded by a variety of human activities. The primary factors include historical gold mining; heavy livestock use of some riparian corridors; vegetation removal on the floodplain; introduction and spread of noxious weeds; road and home development; alterations in the hydrologic regime caused by hydroelectric and water storage reservoirs; gravel mining; and groundwater extraction (Kondolf et al. 1996).

In western Placer County, riparian woodlands occur as well-developed and continuous stands along depositional reaches of Coon Creek and portions of the Bear River and the American River. Along most other creeks, however, this habitat occurs as narrow and generally discontinuous bands of trees (Appendix A). Riparian woodlands rarely occur on intermittent streams and almost never on ephemeral streams that only flow during storm events. Riparian vegetation occupies about 2,456 ha (6,069 ac), or roughly 2% of the land area, in western Placer County (Jones & Stokes 2004a). Accordingly, it is clear that available riparian habitat has been greatly reduced and fragmented, causing a decline in locally nesting populations and an increased potential for local extirpation.

Riparian areas in western Placer County are increasingly surrounded by urban, rural-residential, and agricultural development. Increased noise levels associated with human activity can cause nest abandonment, flushing from the nest, and consequent nest failure (Delaney et al. 1999). Agricultural activities such as mowing, disking, grazing, pesticide use, and artificial flooding can also reduce the habitat quality if they encroach into riparian woodlands (Ohmart 1994). Fragmentation and degradation resulting from urban, residential, and agricultural land uses has probably reduced the wildlife habitat functions of most riparian areas in western Placer County (Appendix A; Jones & Stokes 2004a, 2004b). Urban development can also result in increased mammalian and avian predator populations and greater exposure to predation pressures, as discussed below.

The species richness and densities of certain riparian-associated birds have been demonstrated to decrease with increasing urban development in the surrounding landscape (Rottenborn 1999; Miller et al., 2003). In the uplands of Placer County's foothill oak woodland zone, several riparian-associated bird species (including black-headed grosbeak) were found at lower relative abundance in fragmented compared to unfragmented oak woodland landscapes (Stralberg and Williams 2002).

Livestock Grazing

Livestock grazing in riparian areas is particularly widespread in the western U.S., especially in dry areas where cattle are attracted to riparian zones for water, shade, and shelter (Bryant 1979). Many native bird species have experienced population declines in grazed or heavily settled riparian areas (Tewksbury et al. 2002). Cattle browse and trample riparian vegetation, compact the soil, promote stream bank erosion and loss of water quality, and they attract brown-headed cowbirds (see below). Intensive grazing often increases the fragmentation and degradation riparian habitats, and this leads to a reduction of bird species richness and abundance. During the breeding season, grazing can be particularly detrimental to bird species that nest on or near the ground because cattle disturb understory vegetation and may directly trample nests and/or fledglings (Bock et al. 1993).

Brown-Headed Cowbird Brood Parasitism

The brown-headed cowbird is a native North American species that expanded its range into California in the early 1900s (Grinnell and Miller 1944). Brown-headed cowbirds parasitize the nests of other native songbirds and reduce their reproductive success (Rothstein 1975, Beedy and Granholm 1985, Zeiner et al. 1990a, Gaines 1992, Lowther 1993). Cowbird parasitism contributes to lowered productivity in host species through direct destruction of host eggs and competition between cowbird and host chicks. Brown-headed cowbirds usually parasitize songbird nests that are situated near forest edges (Rothstein et al. 1984, Gates and Evans 1998). However, more recent studies suggest proximity to (within 3.2 km [2 mi]) and occurrence of host species is much more important than the presence of habitat edges, especially in western riparian habitats (Tewkbury et al.1999).

Cattle grazing and other livestock operations attract brown-headed cowbirds. Human habitation, agriculture, and livestock facilities adjacent to riparian zones provide brown-headed cowbirds with ample foraging habitat close to songbird breeding grounds (Tewksbury et al. 1998, Riparian Habitat Joint Venture 2004). In riparian woodlands of western Placer County, brown-headed cowbirds are most common in disturbed areas and in early successional stands, especially where livestock are present nearby (Appendix A). Radio telemetry studies have demonstrated that brown-headed cowbirds may move more than 6.7 km (4.2 mi) between foraging and breeding areas (Rothstein et al. 1984). Daily commute distances of 14 k or more have been reported cowbird abundance has also been shown to decline with increasing distance from human food sources over distances as short as 2 to 4 km (1.2 to 2.5 mi) (Curson et al. 2000).

Predation

The number of young fledged is probably the most important factor influencing the occurrence and persistence of many songbird species. For most species, nest success rates of 20% or less indicate unsustainable or *sink* populations (Donovan et al. 1995).

Proximity to urban and agricultural areas typically leads to higher densities of predators subsidized by human activity, such as raccoons, skunks, feral and domestic cats, jays, crows, and magpies, all of which are well-documented avian nest predators (Zeiner et al. 1990a). Nest predation rates are higher in narrow riparian buffer strips than in intact riparian forests (Vander Haegen and Degraff 1996 but see Haff 2003). Nest predation is higher in smaller woodlots and woodlots near suburban areas than in woodlots in rural areas, and survivorship of most bird species is higher in large forested habitats (larger than 35 ha [86 ac]) than in smaller habitat areas (Doherty and Grubb 2002). Open-cup nests more than 2 m (7 ft) above ground are most vulnerable to predation (Wilcove 1985). A dense and diverse herbaceous or shrub understory provides both nesting sites and protection from predators; this vegetative layer is especially important for species such as spotted towhees, song sparrows, and common yellowthroats that nest on or near the ground (Riparian Habitat Joint Venture 2004).

In general, “soft” edges (e.g., wetland or herbaceous cover grading to shrubs or scrubby willow grading to riparian woodland) are preferable to “hard” edges (e.g., abrupt changes in vegetation type such as agricultural or urban development adjacent to stream corridors), because predation levels along hard edges are higher (Suarez et al. 1997). Manicured parks, rural homes, dairies, and urban areas adjacent to riparian habitat can attract predators and be detrimental to riparian bird populations (Miller et al. 2003). Feeding of wildlife, either inadvertently or intentionally, encourages and elevates populations of nest predators such as domestic and feral cats that are estimated to kill many millions of songbirds annually (Stallcup 1991) and have a major impact on local bird populations (Churcher and Lawton 1987, Coleman et al. 1997).

Introduction of Non-native Species

Introduction of Himalayan blackberry in riparian corridors has reduced the extent of native herbaceous and shrub vegetation in riparian woodlands of western Placer County (Appendix A). This species is the dominant understory plant along many riparian corridors. Although it is not native, Himalayan blackberry is used for nesting, food, and cover by many birds (e.g., California quail, song sparrows, spotted towhees, California towhees, common yellowthroats, and tricolored blackbirds) (Jones & Stokes 2004a), and it may have beneficial effects on some species. Other nonnative plants, such as yellow star-thistle, acacia, black locust, and eucalyptus (blue gum), can outcompete native trees and understory plants that are favored by most bird species (Jones & Stokes 2004a).

Introduced birds such as European starlings, house sparrows, and wild turkeys are widespread in riparian areas of western Placer County. Starling populations are thought to be increasing in the Sierra Nevada foothills (Purcell et al. 2002) and occur throughout the oak woodland landscape in Placer County (Stralberg and Williams 2002). Starlings and house sparrows often outcompete native cavity nesters for nest sites, and turkeys consume foods that might otherwise be used by California quail and other native species (Zeiner et al. 1990a; Purcell et al. 2002).

Black rats and Norway rats occur in riparian woodlands of western Placer County; they are common along urbanized streams that are dominated by Himalayan blackberry thickets (Appendix A). Introduced rats may have detrimental effects on nesting songbirds because they prey on eggs and young, and because they often carry and transmit diseases (Zeiner et al. 1990b).

Mammals

Habitat Relationships

Numerous mammal species are abundant in the riparian woodlands of western Placer County. Up to 41 species breed in these habitats; two other species use them for shelter or foraging. No mammal species are proposed for coverage under the HCP/NCCP for the Phase I Planning Area (Jones & Stokes 2004a).

Mammal species that are often associated with riparian woodlands of western Placer County include vagrant shrew, ornate shrew, Trowbridge's shrew, broad-footed mole, Yuma myotis, California myotis, western pipistrelle, big brown bat, hoary bat, Townsend's big-eared bat, and pallid bat, brush rabbit, black-tailed jackrabbit, western gray squirrel, beaver, western harvest mouse, brush mouse, deer mouse, dusky-footed woodrat, California vole, muskrat, western jumping mouse, porcupine, coyote, gray fox, long-tailed weasel, mink, ringtail, raccoon, American badger, western spotted skunk, striped skunk, river otter, mountain lion (visitor), bobcat (visitor), mule deer, and wild pig (introduced). All these species also occur in a variety of upland habitats in western Placer County (Jones & Stokes 2004a).

Riparian Habitat Requirements

Mammals use riparian woodlands for all scales of movement—as part of their territories or home ranges; as dispersal corridors; or for short-distance movements between breeding, resting, and foraging areas. Conservation biologists often recommend preserving riparian areas for mammals with large home ranges in part because such areas can also function as corridors for dispersal of species with smaller home ranges in fragmented landscapes (Brinson et al. 2002). However, if a riparian woodland does not meet a species' habitat requirements, it may not be used for dispersal and hence will not provide a suitable corridor connecting habitat patches for many large mammals (Noss et al. 1996; Rosenberg et al. 1997; Brinson et al. 2002).

Like territories and home ranges, dispersal capabilities differ among vertebrate groups and species. Large mammals move over large distances, while most species of small mammals (except bats) are relatively sedentary and make only short-distance movements.

Some mammals, such as the ornate shrew, Yuma myotis, beaver, ringtail, raccoon, and river otter are strongly associated with riparian corridors in western Placer County (Table 6-1). Riparian woodlands are also important for migratory mule deer that forage, breed, and take cover there. A source of surface water (e.g., creek or river) is especially important to deer (Zeiner et al. 1990b).

Upland Habitat Requirements

As is true of many bird species, many riparian-associated mammals also frequent nearby upland habitats; most use these areas for breeding, foraging, and cover (Table 6-1). Thus, the adjacent land cover is a strong determinant of the species composition of a specific habitat area. In general, riparian areas that are adjacent to agricultural or urban development have fewer native mammals and an increased density of introduced species such as house mouse, Norway rat, and black rat (Jones & Stokes 2004a).

Patch Size and Riparian Width Requirements

Darveau et al. (2001) found that some large mammal species using riparian strips in Quebec seemed to prefer narrower riparian buffers, while other small mammals preferred wider strips.

Thin (e.g., 20 m [66 ft] wide) strips that connect larger patches can be used as refugia by small and larger mammals. However, narrow strips do not provide sufficient habitat to support mammal species with large territories and home ranges, because such strips exhibit high edge-to-interior ratios (Darveau et al. 2001). Riparian strips at least 100 m (328 ft) wide have been recommended to maintain riparian-associated small mammals, because the presence of these species has been observed to change little with increased width (Hannon et al. 2002).

In western Placer County, most small mammals (e.g., shrews, rabbits, ground squirrels, tree squirrels, mice, woodrats) have relatively small territories and home ranges (less than 1 ha [2.5 ac]) (Zeiner et al. 1990b). However, a few species of larger mammals (coyotes, gray foxes, mountain lions, bobcats, mule deer) occupy large areas, and their home ranges may cover many square kilometers, encompassing riparian woodlands and adjacent oak woodlands, annual grasslands, foothill chaparral, and other upland habitats. For this reason, the extent and quality of upland habitats surrounding riparian habitats is especially important in maintaining breeding populations of these species.

Effects of Human Alterations on Riparian Mammals

Habitat Loss and Degradation

The effects of human-induced habitat loss and degradation on riparian mammals are similar to those described above for riparian-associated birds.

Livestock Grazing

Intensive grazing often increases the fragmentation and degradation riparian habitats, and this leads to a reduction of mammal species richness and abundance. Livestock grazing in streams and their associated riparian corridors affect small mammal populations through direct disturbance and alteration of habitat conditions such as loss of cover and reduced food materials (Ehrhart and Hansen 1997).

Predation

Predation resulting from fragmentation (edge and patch effects) causes effects similar to those described above for birds.

Introduction of Nonnative Species

Nonnative mammals (e.g., house mouse, black rat, Norway rat, Virginia opossum) occur in riparian woodlands in western Placer County (Jones & Stokes 2004a), and they often outcompete native small mammals for food, breeding sites, and cover. In general, riparian woodlands that are situated near urbanized or agricultural areas support the highest densities of these species. Feral cats are widespread in riparian woodlands of western Placer County (Jones & Stokes 2004a, Appendix A), and they prey extensively on small native mammals (Zeiner et al. 1990b). Nonnative plants such as Himalayan blackberry provide habitat for black rats and Norway rats that that may compete with or prey upon small mammals in riparian woodlands.

Reptiles and Amphibians

Habitat Relationships

Up to 18 species of reptiles and four amphibians breed in riparian woodlands of western Placer County. Three other amphibian species (California newt, Pacific treefrog, and foothill yellow-legged frog) visit these habitats during some portions of their life cycles. Two riparian-associated reptiles (western pond turtle and giant garter snake) and one amphibian (foothill yellow-legged frog) may be covered under the HCP/NCCP for the Phase I Planning Area.

Amphibian species that occur in riparian woodlands of western Placer County include: ensatina, California slender salamander, Pacific treefrog, foothill yellow-legged frog, and western toad. Reptiles that may occur in these habitats include racer, common garter snake, western terrestrial garter snake, western aquatic garter snake, common kingsnake, night snake, ringneck snake, California whipsnake, gopher snake, western rattlesnake, western and Gilbert's skinks, southern alligator lizard, and western fence lizard (Jones & Stokes 2004a).

Riparian Habitat Requirements

Most amphibians and some reptiles are closely associated with riparian areas and their associated water bodies. Few terrestrial vertebrates are as dependent on water as are amphibians, since these species require surface water to complete their life cycles. Frogs, toads, and salamanders occur in riparian areas year-round, and intact riparian areas, upland habitats, and aquatic breeding habitats are essential for their survival (Brinson et al. 2002). Reptiles use riparian corridors for cover, shade, and a source of water. Microhabitats in riparian areas are important in meeting the habitat requirements of amphibians and reptiles, and dense, shaded forest canopies and leaf litter are positively correlated with the abundance of these species in narrow riparian corridors (Rudolf and Dickson 1990).

Upland Habitat Requirements

Similar to birds and mammals discussed above, many riparian-associated amphibians and reptiles frequent nearby upland habitats, and can use these areas for breeding, foraging, and cover (Table 6-1). Accordingly, the adjacent land cover is a strong determinant of the species composition of a specific habitat area. Upland habitats can serve as important refugia for reptile and amphibian species during times of flooding. Aquatic turtles will use upland habitats, including forests and flooded agricultural areas, during the warm months (Bodie and Semlitsch 2000). Several species of lizards associated with the vegetative cover and organic material of riparian forests bask and forage in uplands (Brinson et al. 2002). Many snake species hunt in upland habitats, but they rest in cooler microclimates under dense riparian forests (Zeiner et al. 1988).

Patch Size and Riparian Width Requirements

Most reptiles and amphibians in western Placer County have relatively small home ranges and territories (less than 1 ha [2.5 ac]) (Table 6-1). For example, Pacific treefrogs often move only about 10 m (33 ft), and western skinks have average home ranges of only about 0.09 ha (0.22 ac) (Zeiner et al. 1988). In contrast, western pond turtles breed along slow-moving, permanent streams, and they deposit eggs in nests in sandy soils up to 100 m (328 ft) from the streams (Zeiner et al. 1988). Similarly, giant garter snakes may migrate long distances (more than 100 m [328 ft]) from wetland habitats to upland sites that serve as winter hibernacula (Zeiner et al. 1988). Semlitsch and Bodie (2003) recommended a three-tiered approach to conserving habitat for riparian-associated amphibians and reptiles: aquatic buffer (30–60 m [98–197 ft]), core habitat (142–289 m [466–948 ft] including aquatic buffer), and terrestrial buffer (additional 50 m [164 ft] beyond the core habitat to account for the needs of most reptile and amphibian species).

Effects of Human Alterations on Riparian Reptiles and Amphibians

Changes in Flows

Flow diversions or increased streamflows in summer due to water supply and/or releases of treated sewage water could possibly affect amphibians by stranding of tadpoles, washing away or desiccating egg masses, or increasing predation. These effects have been documented for salmonids and foothill yellow-legged frogs (Bauersfeld 1978; National Marine Fisheries Service 1994; U.S. Fish and Wildlife Service 1995, 1996; Kupferberg 1996a; Lind et al. 1996). Water diversions for agriculture also have the potential to entrain tadpoles and other amphibian larvae into irrigation ditches, causing direct mortality. In general, flow and depth affect habitat suitability for riparian-associated amphibians, and reduced flows may confine larvae in remaining pools where they are more susceptible to predation (Hayes and Jennings 1986, 1988).

Habitat Loss and Degradation

In general, the effects of anthropogenic habitat loss and degradation on riparian reptiles and amphibians are similar to those described above for riparian-associated birds. However, inputs of fine sediment from adjacent land uses may also detrimentally alter the aquatic habitats of amphibians (Ashton et al. 2003).

Livestock Grazing

Livestock grazing in riparian corridors affects reptile populations through direct disturbance and alteration of habitat conditions. However, these effects may not result in differences in reptile and amphibian species richness or abundance between grazed and ungrazed sites (Homyack and Giuliano 2002).

Predation

Predation as a result of fragmentation (edge and patch effects) probably is greater in agricultural and urbanized areas than in riparian forests surrounded by oak woodlands or other upland habitats. The introduced bullfrog is a major predator of adult and larval amphibians (see discussion below).

Introduction of Nonnative Species

Bullfrogs are the only introduced, nonnative amphibian species in western Placer County. They were observed on about 25% of the riparian plots that were surveyed in the course of this study (Appendix A). Bullfrogs frequently prey on the larvae and adults of native amphibians, and they compete with native amphibians for space and food (Zeiner et al. 1988). Bullfrogs may be responsible for the elimination of California red-legged frogs and foothill yellow-legged frogs from the floor of the Central Valley and much of the Sierra Nevada foothills (Moyle 1973; Kupferberg 1996b). There are no introduced reptiles in western Placer County (Jones & Stokes 2004a).

Relationships Between Setback Width and Effects of Human Alterations

Some effects of human-induced alterations (e.g., abrupt flow changes) do not vary with riparian width, and their effects on terrestrial vertebrates are not well understood. However, many other relationships between riparian area width and animal diversity have been well documented. The effects that are most strongly related to setback width and the total area of riparian plots are direct habitat losses and fragmentation of riparian corridors. Many riparian species require a minimum area of contiguous habitat that must contain specific habitat attributes (e.g., interior forest microclimate, upland refugia, large trees, snags). In order to conserve wildlife habitat functions, the width of riparian areas must be sufficient to contain these habitat attributes for area-sensitive species.

Habitat requirements vary considerably among various riparian-associated vertebrate taxa. However, the following general conclusions can be made regarding the relationship of habitat values to width and size of riparian areas in western Placer County.

- Large (more than 10 ha [25 ac]) and wide (more than 500 m [1,640 ft]) riparian corridors provide the highest habitat values for riparian-dependent wildlife with large home ranges and territories.
- Moderately large (5–10 ha [12–25 ac]) and wide (more than 100 m [328 ft]) corridors provide sufficient habitat values to support most native species that are strongly associated with these habitats.

- Small (less than 5 ha [12 ac]) and narrow (less than 30 m [98 ft]) riparian corridors provide habitat values for many species, but most area-sensitive species will probably not be present.
- Highly fragmented and narrow riparian corridors (< 5 m [16 ft]) provide habitat for only a few generalist species, but they may still provide some values for cover and as movement corridors in urbanized and agricultural areas.

Recommendations for Setbacks to Conserve Terrestrial Animal Functions

In view of the foregoing, the project team recommends the following management strategies to conserve wildlife habitat functions.

- Low order streams (i.e., first and second order stream segments), which typically have narrow riparian corridors, should be managed to maintain and enhance riparian corridors at least 30 m wide. Where only very narrow (e.g., < 5 m [16 ft] wide) riparian corridors are feasible, these narrow areas should still be conserved because they may function as dispersal corridors.
- Higher order stream segments (i.e., third order and higher), which often have broader riparian corridors, should be managed to maintain and enhance riparian corridors at least 100 m (294 ft) on both sides of the channel (Semlitsch and Bodie 2003, Appendix B). Riparian woodlands should be restored and enhanced within this zone. Restoration and enhancement measures should include:
    - Re-creation of regular disturbance events (e.g., high water) on the floodplain will enhance vegetation and breeding bird populations in most systems (Riparian Habitat Joint Venture 2004).
    - Management activities such as mowing, grazing and burning within riparian zones should be limited to the non-breeding season to minimize impacts on nesting birds (Riparian Habitat Joint Venture 2004).
    - Other recommendations listed in (Riparian Habitat Joint Venture 2004).
- Where feasible, contiguous areas larger than 5 ha (12 ac) should be maintained, enhanced and linked to provide habitat refuge areas for area-sensitive species. These areas should be connected by riparian corridors more than 30 m (98 ft) wide on both sides of the channel wherever possible, in order to provide movement and dispersal corridors for wildlife.
- Where large, wide riparian corridors are not feasible in urbanized and/or agricultural settings, a minimum riparian buffer width of 10 m (33 ft) should be maintained to provide movement corridors for generalist species (Riparian Habitat Joint Venture 2004).

- Riparian woodland edges should be minimized (e.g., patches rather than linear strips) and buffered by shrubs and forbs (to reduce predation pressure on open-cup nesting species (RHJV 2004, Small et al. 1999).
- Streams should be prioritized for preservation and/or enhancement based on the information summarized herein. Some streams currently have higher wildlife value than others (e.g., Coon Creek) and should be the conservation priority.
- Non-native plants and animals, especially nest predators (e.g. rats, raccoons, domestic and feral cats), should be reduced and controlled on riparian-adjacent properties (Riparian Habitat Joint Venture 2004).
- The preservation, restoration and linkage of large parcels of undeveloped and uncultivated lands adjacent to riparian areas will provide significant benefits to riparian songbird species. Thus, large contiguous areas of riparian vegetation surrounded by "natural" uplands should be conserved to the greatest extent possible.
- Potential effects of adjacent land uses on riparian areas should be thoroughly evaluated during regional land use planning, and during the environmental review and permitting processes for specific projects, and these effects should be avoided to the maximum extent practicable.

It is important to recognize that riparian setbacks are not sufficient to ensure habitat functions for all wildlife species. Many factors affecting wildlife habitats are unrelated, or only indirectly related, to setbacks; such factors include the condition of the riparian vegetation and the abundance of nonnative plants and animals. Landscape factors can have significant effects on riparian areas (Allan 2004, Appendices A and B of this report). For example, adjacent land uses, such as intensive grazing, human habitation, golf courses, and agriculture, can significantly subsidize predator populations that can then turn to the riparian zone for sustenance (Riparian Habitat Joint Venture 2004).

Currently, most riparian areas in western Placer County have been affected by human alterations. Even where moderately wide sections (i.e., more than 100 m [328 ft]) of riparian vegetation remain, wildlife habitat functions and species richness and abundance may be reduced compared to large and wide riparian corridors that are surrounded by native vegetation (Appendices A and B). Therefore, conservation of wildlife habitat functions in western Placer County's riparian areas will require the implementation of measures involving the management of adjacent land uses as well as streams and riparian vegetation within defined setbacks.

Chapter 7
Overall Recommendations for Riparian Setbacks

Riparian setbacks should be adequate to provide long-term conservation of riparian and stream functions in western Placer County. However, while width criteria for setbacks are particularly important, other criteria should address the compatibility of existing and future land uses within these setbacks with the conservation of riparian and stream functions. Setbacks are essential for the conservation of riparian and stream functions, but they are not in themselves sufficient to ensure successful conservation of these functions. For this reason, additional measures also will be necessary to conserve these functions.

Conclusions Regarding Riparian and Stream Functions

Based on the review and analysis of riparian and stream functions, the effects of human alterations on such functions, and the relationships between these effects and setback widths, the project team identified the following 10 conclusions that are particularly relevant for setback criteria.

- Stream channels move within their active floodplains.
- Changes in runoff and erosion from uplands affect hydrologic and biogeochemical functions of streams.
- Patterns of groundwater flow affect biogeochemical functions (e.g., nitrate and phosphorus removal, degradation of SOCs); these patterns can be complex in both active and historic floodplains.
- Erosion of sediment is a major pathway by which contaminants enter streams.
- Sediments stored on active floodplains may remain there temporarily until floodwaters carry them into stream channels.
- Periodic floodplain inundation is important for salmonid and riparian plant habitat functions.
- Riparian vegetation is dynamic: it is frequently removed by disturbances, grows rapidly, and is sensitive to water availability.

- All riparian and stream functions are affected by artificial structures, impervious surfaces, ground disturbance, and removal of natural vegetation within stream channels or active floodplains.
- Riparian-associated wildlife species differ in the specific habitat attributes they require in riparian systems. Consequently, structurally diverse vegetation, as well as the full range of naturally occurring physical conditions and disturbance regimes, are necessary to provide suitable riparian habitat for the entire community of associated wildlife species.
- Many riparian-associated wildlife species use, and often require, both riparian and adjacent upland habitats for reproduction, cover, and/or foraging.

Rationale for Including Active Floodplains in Setbacks

These conclusions regarding riparian and stream functions, considered collectively, indicate that most human uses of the active floodplain are not compatible with conservation of riparian functions, because the stream and its floodplain represent an integrated system that, when intact, produces riparian functions. Accordingly, development and encroachment setbacks should include the entire active floodplain of a creek or river. (The active floodplain is the geomorphic surface adjacent to the stream channel that is typically inundated every 2-10 years or less.)

These conclusions also indicate that active floodplain boundaries are more stable and measurable than stream banks or the boundaries of riparian vegetation that are dynamic and change with time. Therefore, the boundary of the active floodplain, which can be readily delineated, is a preferable basis for determining setback widths than are the edges of stream banks, stream centerlines (or thalwegs), or any boundaries based exclusively on channel widths or vegetation.

Rationale for Including Lands Adjacent to Active Floodplains in Setbacks

The conclusions regarding riparian and stream functions indicate that lands adjacent to active floodplains provide physical and habitat functions, and they help to buffer streams from excessive inputs of sediment and contaminants. In general, conservation of most terrestrial wildlife functions depends on the inclusion of land beyond the active floodplain to provide adjacent upland habitats that benefit many riparian-associated wildlife species, and to buffer riparian habitats from the effects of adjacent land uses.

In western Placer County, riparian vegetation currently provides wildlife habitat outside the active floodplains of rivers and creeks. Such vegetation can occur on historic floodplains that have become isolated from streams due to changes in flows and channel form. Construction of levees or berms also causes isolation of riparian vegetation. Some of this adjacent vegetation would be within setbacks that include land outside the active floodplain. Adjacent lands would also buffer riparian and stream ecosystems from inputs of sediments and contaminants through infiltration of runoff and retention of sediment. Along the smallest channels, whose floodplains are very narrow (or essentially absent), this additional buffer is necessary to prevent inputs from entering the stream channel directly.

There is no single, abrupt, well-documented threshold width setback that would provide maximum benefits for all riparian functions. Rather, because riparian functions have different mechanistic bases, they are affected by different site attributes, and the relationship between setback widths and reduction of human effects differs among riparian functions. These relationships are described in detail in Chapters 2-6.

Nevertheless, several defensible arguments can be constructed regarding the appropriate width for a buffer to include within riparian setbacks. First, most riparian functions would be affected if setbacks included a buffer of less than 20 m (66 ft) beyond the active floodplain; consequently, narrower widths are not adequate for long-term conservation of riparian functions. This conclusion is based largely on our review of the scientific literature (summarized in Chapters 2-6). In addition, in western Placer County, stream incision and a discontinuous cover of woody plants reduces the benefits of narrow buffers. Recent incision now restricts the active floodplain to a narrow band along many of the higher order stream segments in western Placer County (Jones & Stokes 2004c, Placer County Planning Department 2002). Thus, a narrow setback would not include large areas of riparian vegetation on the historical floodplain. Also, the riparian vegetation of western Placer County has a lower and more discontinuous cover of trees and shrubs than do many of the sites where research has been conducted (Appendix A). For many functions (e.g., cover for terrestrial wildlife), this variability in vegetation extent and structure reduces the effectiveness of narrow setbacks.

Second, while there is evidence that even buffers wider than 30 m (98 ft) are not sufficient to eliminate detrimental effects altogether, the benefits provided by additional width beyond 30 m (98 ft) are either small or represent diminishing returns for most functions. For example, in western Placer County, riparian (and most upland) trees reach only 20-30 m (66-98 ft) in height. Thus, at distances > 30 m (98 ft) trees provide very little woody debris to stream ecosystems, and cast little shade on streams.

Third, unlike most other functions, the conservation of wildlife habitat functions for some area-sensitive species requires buffer areas substantially wider than 30 m (98 ft) beyond the active floodplain. This is illustrated by the summary in Table 6-1 of the habitat requirements and area requirements of riparian-associated wildlife in western Placer County. Significantly, wildlife habitat functions also differ from most other functions because the setbacks necessary to conserve them do not necessarily have to be applied along the entire stream network in order to be beneficial. Most wildlife habitat functions probably could be conserved in western Placer County by means of extensive sites with wider setbacks (> 100 m [328 ft]) connected by stream corridors with narrower setbacks (e.g., 30 m [98 ft]).

Recommendations for Riparian Setback Widths in Western Placer County

The project team's overall recommendations for riparian setbacks are presented below.

- Apply to first and second order stream segments a minimum riparian setback that includes the entire active floodplain plus a buffer of 30 m (98 ft) of adjacent land (on each side of the active floodplain), or the distance to the nearest ridgeline or watershed boundary, whichever is less. (First order stream segments are upstream segments that have no tributaries, and second order segments are formed by the junction of first order segments.) Though the purpose of this setback would be to conserve stream and riparian functions; it would not be sufficient for the conservation of many wildlife species with large area requirements.
- Along higher order stream segments (i.e., third order and greater), and along lower order segments at selected sites (e.g., those in or adjacent to conservation lands), apply a setback of at least 100 m (328 ft), and preferably 150 m (656 ft), from the active floodplain for the purpose of conserving and enhancing stream and riparian ecosystem functions including most wildlife habitat functions. Along these larger stream segments, floodplains and riparian areas are more extensive, continuous, and structurally diverse than for lower order stream segments (e.g., first and second order). These areas constitute corridors connecting a watershed's lower order stream segments, and, at a watershed scale, the riparian areas of these higher order segments contain particularly important habitats for most riparian-associated species. The conservation of wildlife habitat functions within these areas may be necessary for the persistence of their populations within western Placer County. For this reason, a wider setback, sufficient for the retention of wildlife habitat functions, is recommended along these stream segments.

The team estimates that these recommendations would result in a total setback width ranging from slightly more than 30 m (98 ft) on most first- and second-order stream segments to over 150-200 m (492-656 ft) on higher-order streams near Placer County's western boundary. (Widths > 150 m (656 ft) would be associated with the 150 m setback suggested for higher order stream segments in the overall recommendation above.) This estimate is based on a preliminary examination of riparian vegetation as shown on aerial photographs and of mapped alluvial soils; such soils indicate the extent of the historic floodplain, which in many cases is wider than the current active floodplain. The project team did not measure active floodplains in the field. However, widespread incision limits active floodplains to a fraction of the historical floodplain of along several of the larger streams (Jones & Stokes 2004c, Placer County Planning Department 2002).

By basing these recommendations, in part, on the width of active floodplains, the project team has created a variable, site-specific setback width that accounts for stream size. The width of the active floodplain provides a clear, functional basis for a variable width criterion that accomplishes the same purpose more directly than criteria based on stream order, slope, and other attributes of streams and their settings.

Management Recommendations for Riparian Setbacks

Within these setbacks, most developed land uses would be incompatible with the conservation of stream and riparian functions. Within the active floodplain, developed land uses should be restricted to unavoidable crossings by roads and other infrastructure, because any structures or alterations of topography, vegetation or the soil surface are likely to affect both stream and riparian functions, and could result in substantial effects both on-site and downstream.

Within the portion of a setback that is outside of the active floodplain, some uses could be compatible with conservation of riparian functions, particularly along first- and second-order streams where conservation of salmonid and wildlife habitat are not necessarily the primary objectives. Along first- and perhaps second-order streams, compatible agricultural uses include filter strips and riparian buffers managed according to standards established by the National Resources Conservation Service. Such practices would improve the buffers' effectiveness for conserving some functions; additionally, there are programs that subsidize the establishment and maintenance of such practices. Along first- and perhaps second-order streams, compatible developed land uses could include public open space, landscaping, and low-density residential development, provided that no impervious surfaces, infrastructure, or irrigation are placed within the setback.

Within the wider setbacks for wildlife conservation, some additional development > 30 m (98 ft) from the active floodplain could be incorporated at sites with limited conservation value. Though development within these setbacks generally is not compatible with the conservation of wildlife habitats, extensive areas of developed and agricultural lands already exist along streams in western Placer County. Thus, effective conservation of some sites may be very problematic, and it may be more appropriate to mitigate offsite for the loss of habitat caused by development of these sites, than to preclude this development (and thus potentially cause the loss of habitats elsewhere). Such mitigation could contribute to the conservation of more extensive areas along relatively unaltered stream reaches.

In the absence of additional site-specific information, effects on riparian wildlife habitats due to adjacent development could be considered to diminish with distance from the active floodplain or existing riparian area. Effects would be greatest due to development of immediately adjacent land and would drop to minimal levels at 100-200 m (328-656 ft) away. There are several reasons for considering effects to be related to distance. First, the magnitude of effects on the processes sustaining riparian habitats diminishes with distance. Second, most riparian-associated wildlife species also use upland habitats and the area of adjacent uplands is greater when development is more distant. Third, harm and harassment due to pets and people probably diminishes with distance. Fourth, roads and structures are less likely to affect animal movements along the riparian corridor if at a greater distance from it. These and other relevant mechanisms are described in detail in Chapters 2-6 of this report.

Currently, agricultural and developed land uses exist within the recommended setbacks, and they preclude the effectiveness of the recommended setbacks in these areas. For example, along the major streams of western Placer County, approximately a quarter of the land < 20 m (66 ft) from the centerline of a stream, already is in developed or agricultural land-cover (Jones & Stokes 2004a, 2004b). For some functions (e.g., biogeochemical and hydrologic functions), this limitation cannot be offset by establishing wider setbacks in other areas (Weller et al. 1998).

In addition, there are other, more fundamental limitations on the effectiveness of setbacks for conserving riparian and stream functions. Examples of these limitations include the effects of dams and flow diversions, currently abundant nonnative species, mercury from the Gold Rush era already in riparian and stream sediments, and runoff that bypasses riparian areas by passing through the stormwater system directly into streams. Also, conversion of large portions of a watershed or region to developed and agricultural land uses is associated with broad negative effects on riparian and stream ecosystems (Findlay and Houlahan 1996, Roth et al 1996, Booth and Jackson 1997, Magee et al. 1999, Doyle et al. 2000, Paul and Meyer 2001, Allan 2004, Hatt et al. 2004, Pellet et al. 2004, Wissmar et al 2004, and Appendices A and B of this report).

Addressing these and other effects on riparian and stream functions will require additional conservation measures. These additional measures include measures for the:

- design and operation of stormwater and water supply systems to minimize impacts on hydrologic and geomorphic functions;
- implementation of construction and agricultural Best Management Practices (i.e., BMPs) to prevent excessive erosion and high inputs of fine sediments to floodplains and streams.

- maintenance and enhancement of riparian vegetation and it's habitat values (as described in Chapter 6); and
- preservation of extensive areas of natural vegetation, particularly in and adjacent to riparian corridors.

The implementation of such measures would both complement, and greatly enhance, the benefits provided by riparian setbacks for the conservation of stream and riparian functions.

Summary

This report summarizes the relationships between riparian site attributes and biodiversity in the data sets collected in Tasks 2.8 (Evaluation of Habitat Assessment) and 2.10 (Validate RAP and Habitat Assessment) for the Placer County Riparian Ecosystem Assessment. More specifically, for one-hectare (2.5 acres) plots located in riparian corridors of the Sacramento Valley and adjacent foothills, we describe the relationships between species richness (i.e., number of species) of selected taxonomic groups (i.e., birds, mammals, reptiles, amphibians, butterflies, dragonflies, and damselflies) and measured vegetation and land cover attributes. The primary goals for collecting and analyzing these data were to support the development of a functional assessment model (FAM) for riparian habitats in Placer County, and to provide setback guidance for riparian corridors in western Placer County. The key results of the study were:

- vertebrate data from multiple site surveys provide a much stronger basis for assessing a riparian site than do data from a single site visit;
- non-destructive area searches for mammals, amphibians, and reptiles were not effective rapid assessment survey techniques, even with the placement of cover boards to provide artificial shelter for these species;
- for the 50 riparian sites surveyed, species richness was not strongly correlated among the different taxonomic groups, nor was the width or structure of the riparian vegetation strongly correlated with richness for any taxonomic group; however
- land cover in the vicinity (i.e., within 250 meters to 5 kilometers) of plots was related to the species richness of several taxonomic groups we examined, and in some cases, these relationships were strong.

These results have implications for the development of a riparian FAM and for guidance regarding riparian setbacks. However, they should be interpreted with caution since they were based on a small sample size (e.g., only 12 plots were visited for multiple surveys), a large geographic area was covered, and only presence data were collected for species in each taxonomic group. (In addition, several published studies are not consistent with some of our conclusions.) Assessment of overall riparian habitat functions should not be based on a single taxonomic group because none indicates the overall habitat functions provided by a site and responses vary within each taxonomic group. Also, assessments of habitat values should consider, attributes of surrounding land cover, in addition to attributes of the riparian vegetation itself. Similarly, the basis for setback widths should consider the upland habitat requirements of riparian species and the effects of adjacent upland land uses on riparian habitat, as these factors have

significant relationships with species richness of riparian-associated species for at least several taxonomic groups (e.g., birds, dragonflies, and butterflies). Separate technical reports will propose a draft FAM and will provide guidance regarding riparian setbacks. The implications of this study will be considered more fully in these reports.

Relationships Among Animal Species and Site Attributes in Riparian Ecosystems of the Sacramento Valley, California

Introduction

This report summarizes the results of Tasks 2.8 (Evaluation of Habitat Assessment) and 2.10 (Validate RAP and Habitat Assessment) of the Riparian Ecosystem Assessment that Jones & Stokes is conducting for the Placer County Planning Department, with assistance from the Point Reyes Bird Observatory (PRBO). These tasks were intended to support development of assessment techniques, preparation of a functional assessment model (FAM) and summarizing setback guidance for the riparian corridors of western Placer County. These tasks involved collection of data on species presence and site attributes at a random sample of riparian sites in Placer County and throughout the Sacramento Valley. Task 2.8 consisted of a field and geographic information systems (GIS) assessment of 47 sites. Task 2.10 consisted of additional, more intensive, data collection (including multiple surveys) at 12 of these sites.

Our analyses of these data focused on the relationships typically serving as the basis for setbacks and indicator-based assessments. Some FAMs base their measures of terrestrial habitat functions on the presence of selected taxa (e.g., bird species) that are presumed to indicate habitat suitability for other taxonomic groups. However, most FAMs are based on a combination of site attributes that are predicted to influence habitat area or quality for most species. The widths of riparian setbacks that are intended to conserve habitat functions are based on the relationships between species presence and the area of habitat types and the potential influence of adjacent land uses. Therefore, we examined criteria for assessments and setbacks by comparing the relationships among the species richness of taxonomic groups and their relationships to measured site attributes. Our general hypotheses were:

1. The number of riparian–associated bird species (riparian bird species richness) is positively associated with the species richness of other vertebrates and of invertebrates (i.e., bird species richness is a valid indicator of overall biodiversity);

For all taxonomic groups:

2. Species richness increases with the width of riparian vegetation;

3. Species richness increases with the cover of woody plants (i.e., trees and shrubs) in the riparian vegetation;
4. Species richness increases with the total area of riparian vegetation in a plot and its surrounding landscape;
5. Species richness increases with the proportion of surrounding land area in natural vegetation; and
6. Species richness is negatively associated with the proportion of developed and agricultural land uses in the surrounding landscape.

For our analysis of birds and butterflies, we included only riparian-associated species, which are presumably more responsive to riparian site attributes than other species that may use a range of habitat types, including riparian. We considered riparian-associated birds and butterflies to be those species that in the Sacramento Valley and adjacent foothills are primarily associated with riparian vegetation (Tables 1 and 2). These lists were determined prior to field work on the basis of relevant literature (Pool and Gill 1990–2003) and our professional judgments; the draft bird list also was revised in response to comments by PRBO ornithologists.

Methods

In addition to the following summary, our sample design and data collection methods were described (in more detail) in the sample design memo and field protocols provided to the Placer County Planning Department in 2003 (Appendix A).

Sample Design

Study site locations (plots) were a stratified random sample of existing PRBO point count survey sites along tributary streams in the Sacramento Valley where information regarding riparian corridor width was available and site access was know to be possible. Additional plots in Placer County were also included in cases where permission to enter private lands had been granted. Although not along a tributary stream, PRBO sites along the Cosumnes River were included in the list of potential plots because this area was considered reasonably similar to many of the included tributary streams in its riparian attributes. This set of potential plots was stratified on the basis of riparian corridor width. Data from PRBO records, digital aerial photographs, and a draft land cover map of Placer County were used to assign each plot to a width category. These categories were: 0–20 meters (m), >20–40 m, >40–60 m, >60–100 m, and >100–200 m. From each width category, ten plots were randomly selected, each at least 500 m from all other selected plots.

Sample size was limited by access to suitable survey sites and the available budget. On this basis, we estimated the maximum sample size would be 50 plots.

The power associated with this sample was sufficient to identify correlations between variables (power > 0.8 for even small values of *r*); however, it was of more marginal size for the application of multivariate analyses, such as multiple regression analyses. Statistical power is the ability of a statistical test to the identify relationships and differences that exist (i.e., it is the ability to reject the null hypothesis of no difference or association when it is incorrect).

From those plots located on Placer County, public or Nature Conservancy properties, 12 were randomly selected as more intensive data collection plots, each at least 5 kilometers (km) apart. At these plots, in addition to the data collection taking place at other plots, the following surveys were performed: small mammal trapping; placement of cover boards that might be used as artificial shelters for amphibians and reptiles; and multiple surveys for butterflies and vertebrate groups. These data collection plots were included in the study, despite their cost, to allow the value of this additional data to be evaluated. However, for these additional data, the small sample size substantially limits the analyses that can be applied, the power of these analyses, and thus the conclusions that can be drawn from the data. For example, the power associated with data from these 12 plots was only sufficient for the identification of strong correlations (i.e., *r* values > 0.7), and important combinations of site attributes had few or no replicates.

During our study, access or scheduling difficulties prevented most data collection at three plots, and seven plots were not surveyed for odonates. Thus, sample sizes were reduced to $n = 47$ and to $n = 43$ for odonates.

Field Data Collection

A 1-ha plot (100 m by 100 m) was located along the bank of the stream channel at all of the study sites. These plots contained riparian vegetation, and most also contained other natural, or agricultural or developed land-cover. For each plot, information on site attributes was recorded and area searches were conducted for vertebrate and invertebrate species.

The site attributes recorded in the field included: onsite infrastructure, disturbance, vegetation, surrounding land use, and evidence of overbank flows (Appendix A). Presence of infrastructure (roads, bridges, levees, or bank protection) and evidence of disturbance (grazing, trash dumping, cutting of trees and shrubs, etc.) were recorded for the riparian and non-riparian portions of the plot and for lands within 250 m of the plot. (The riparian portion of the plot was defined as the zone covered by riparian trees and shrubs.) For the riparian vegetation within the plot, we recorded its width along the stream (at the plot’s edges and center), cover of the tree, shrub and herb layers, and the cover of each woody species, as well as snag density, and predominant tree size class. We also recorded the length and continuity of riparian vegetation along the stream corridor, and estimated the percent of adjacent land (within 250 m) that was in natural vegetation, agricultural, and developed land cover types.

Standardized, time-constrained area searches (Ralph et al. 1993) were conducted separately for vertebrate and invertebrate species (see Appendix A for protocols). For vertebrates, searches of the entire plot were conducted for one hour (between 6 and 11 a.m.) on one day between mid-May and mid-June, 2003. However, at 12 intensive data collection plots we conducted area searches four times at approximately one-week intervals from mid-May to July 1. During the area searches, we recorded all species observed, and species for which scat or tracks were observed, and noted whether the species was observed in the riparian or non-riparian portions of the plot. Woody debris and rocks were not disturbed to avoid degrading habitat. For birds, we also recorded total numbers of individuals and observed behaviors (e.g., territorial displays, carrying food or nesting material, or observation of nests). Observed behaviors (and presence of nests or fledglings) were used to identify potential residents, and the number of potential resident species among riparian-associated birds was included in the analysis. Point counts (Point Reyes Bird Observatory 2003) also were conducted at plots in Placer County because no PRBO point count data existed for those locations.

Each plot was also surveyed twice for butterfly species, once during May 15–30 and again during June 2–14, 2003 and most plots (43 of 47) were surveyed once for odonates (i.e., dragonflies and damselflies) during August 19-29, 2003. These searches were conducted between 9 a.m. and 4 p.m. because of the daily flight activity patterns of these animals. As with the vertebrate area searches, the odonate and first butterfly surveys at each site were one hour long and each observed species was recorded. For butterflies, the number of observed individuals also was recorded. Based on the results of the first butterfly survey and to reduce costs, the second survey at each site was shortened to 50 minutes. (This caused no complications for the testing of our hypotheses because each site received equal survey effort.)

Small mammal live-trapping was also conducted at the 12 intensive data collection sites. Along the length of the plot's streambank side, 15 Sherman live traps were evenly spaced. An additional 15 traps were placed along a second line 10 m away and parallel to the first trap line. Each trap was baited with peanut butter and rolled oats, and a wad of cotton was placed at the back of each trap for bedding. These traps were set within 2 hours of sunset and checked within 3 hours of sunrise on three consecutive nights between June 10 and July 3, 2003.

At the 12 intensive data collection sites, cover boards also were placed within plots (Fellers and Drost 1994). These cover boards were approximately 0.9-m by 0.6 m pieces of 1.9 centimeters (cm) thick plywood. Along the length of the plot's streambank side, 10 cover boards were evenly spaced. An additional 10 boards were placed along a second line 10 m away and parallel to the first. These boards were lifted during each area search to determine the presence of amphibians and reptiles.

Geographic Information Systems Data Collection

In addition to site attributes recorded in the field, GIS data layers were used to estimate the area of four land cover types within 250 m, 1 km, and 5 km of each plot center including: riparian vegetation, natural vegetation (including riparian), developed, and agricultural land cover types. For this analysis, we used the best available data for each plot's location in the Sacramento Valley. These land cover data were from the California Department of Fish and Game's Wetland and Riparian GIS Mapping Layers (Ducks Unlimited 1997), Sacramento River riparian vegetation (California Sate University Chico 1998), U.S. Forest Service existing vegetation (U.S. Forest Service 1999–2000), California Department of Water Resources' land use layer (California Department of Water Resources various years), and the Draft Land Cover Map of Western Placer County (Jones & Stokes 2004). The process by which a single coverage was produced from these data sources involved converting each data source from its vector format to a 31 m grid. For tabulating the area of riparian vegetation within 250 m, 1 km and 5 km, cells attributed as riparian in any of the data layers were counted as riparian. Surrounding land use information was calculated from the California Department of Water Resources land use layer. This layer was a composite of counties that were photographed and mapped in different years. The land use categories in this layer were aggregated into three broad categories: natural vegetation, and agricultural and developed lands.

Data Analysis

Our data analysis consisted of summarizing the data sets and testing our six general research hypotheses. In evaluating these hypotheses, we used scatter plots, correlation coefficients, and simple or multiple stepwise regression models (Sokal and Rolf 1994). All statistical analyses were performed with the S-Plus statistical software package (MathSoft, Inc. 1999).

We evaluated our hypotheses with respect to eight species groups: 1) All bird species; 2) Riparian-associated bird species; 3) All mammals; 4) Small mammals; 5) All amphibians and reptiles; 6) All butterflies; 7) Riparian-associated butterflies; and 8) all odonates. For all of these groups (except small mammals), species richness (i.e., number of species) was used as the measure of the habitat provided for that group at an individual site. In other words, species richness was analyzed with respect to the amount, quality and diversity of habitat. Density of trapped individuals was the metric used for small mammals.

Our conclusions were based on the results of these analyses, consideration of the data's limitations (due to methodology and sample size) and a review of applicable scientific literature.

Table 1. Riparian-Associated Birds of Western Placer County

Common Name	Scientific Name
Cooper's Hawk	*Accipiter cooperii*
Red-shouldered Hawk	*Buteo lineatus*
Swainson's Hawk	*Buteo swainsoni*
Black-chinned Hummingbird	*Archilochus alexandri*
Downy Woodpecker	*Picoides pubescens*
Western Wood Pewee	*Contopus sordidulus*
Willow Flycatcher	*Empidonax traillii*
Pacific-slope Flycatcher	*Empidonax difficilis*
Warbling Vireo	*Vireo gilvus*
Tree Swallow	*Tachycineta bicolor*
House Wren	*Troglodytes aedon*
Yellow Warbler	*Dendroica petechia*
Common Yellowthroat	*Geothlypis trichas*
Yellow-breasted Chat	*Icteria virens*
Song Sparrow	*Melospiza melodia*
Black-headed Grosbeak	*Pheucticus melanocephalus*
Blue Grosbeak	*Guiraca caerulea*
American Goldfinch	*Carduelis tristis*

Table 2. Riparian-Associated Butterfly Species

Common Name	Scientific Name
Sara Orange-tip	*Anthocaris sara*
Pipevine Swallowtail	*Battus philenor*
Lorquin's Admiral	*Limentis lorquini*
Mourning Cloak	*Nymphalis antiopa*
Two-tailed Swallowtail	*Papilio multicaudatus*
Western Tiger	*Papilio rutulus*
Umber Skipper	*Paratrytone melane*
Green-veined White	*Pieris napi*
Satyr Comma	*Polygonia satyrus*
Sylvan Hairstreak	*Satyrium sylvinus*
Red Admiral	*Vanessa atalanta*
California Dogface	*Zerene eurydice*

Prior to calculating correlation coefficients or constructing regression models, variables were transformed to improve normality and homogeneity of variances. Percents were arcsine transformed, areas and widths were log transformed, and count data were square root transformed (Sokal and Rolf 1994; Zar 1999). Correlation coefficients were used to evaluate the magnitude and significance of relationships between pairs of variables. (Magnitude is the degree that two variables co-vary, while significance indicates that the correspondence is unlikely to have occurred by chance.) We used these coefficients to evaluate relationships among plot attributes, the different species groups, and between species groups and plot attributes.

Regression models were also used to evaluate the strengths of relationships between plot attributes and the measured species richness of taxonomic groups. A least-squares regression model is the equation for the straight line that best "fits" the data. This is the line that comes as close to passing through the data points as is possible. Unlike correlation coefficients, regression models can be used to quantify the degree to which combinations of readily observed plot attributes could be considered predictors of species richness. The interpretation of each regression model was based on its R^2 value and the partitioning of the sum of squares among variables (i.e., the sum of the squared deviations from the mean). In developing a regression model for each species group, species richness was the dependent variable and 1–4 plot attributes were the independent variables considered. Only variables significantly correlated with a group's species richness ($\alpha = 0.05$) were considered for initial inclusion in a model. When two or three variables representing an adjacent land cover type (e.g., percent natural vegetation within 250 m and within 1 km) were correlated with a species group, only the variable with the highest correlation was included. This was done to avoid including strongly correlated independent variables that could complicate interpretation of the results. Stepwise multiple regression analysis was used to define the final regression model if two or more variables were included in the initial model.

In interpreting the statistical significance of relationships, we adjusted the threshold for significance to account for making multiple statistical comparisons to evaluate one research hypothesis. Traditionally, a P value < 0.05 is used to indicate statistical significance. However, as more statistical tests are performed the odds of encountering a low P value due to chance increase. Therefore, we adjusted the P value considered significant through a Bonferroni correction (Sokal and Rolf 1994) so that the probability of erroneously considering a result significant (i.e., when the pattern was due to random variation in the absence of an actual relationship) was < 0.05 for the entire set of statistical tests addressing one of our general research hypotheses. Each of our hypotheses was addressed by 8–24 statistical comparisons, therefore, P values of 0.0063–0.0021, respectively, were considered the thresholds for significant relationships. Since Bonferroni adjustments are sometimes criticized as being overly strict, especially when the consequences of false negatives (β error) are worse that the consequences of false positives (α error), P values above these thresholds but < 0.01 were considered suggestive of possible relationships among the variables.

Although more than one dependent variable (i.e., richness based on one or four site surveys) was analyzed for several of the species groups, not every variable was used to evaluate any one of our research hypotheses. Because few mammal, amphibian or reptile species were detected over the course of a single area search, we only used richness based on four visits for these species groups.

Results

Most of the plots were situated in moderately to substantially altered riparian corridors, including Placer County plots (Table 3, Appendix B). At only 2 of the 47 plots (4%) was riparian vegetation > 100 m wide. Only 6 of the 47 plots (13%) were completely surrounded by natural vegetation and did not contain any infrastructure. In contrast, for 16 plots (34%) agricultural or developed land accounted for over half the adjacent land cover within 250 m, and 44% contained a road or other infrastructure (Table 3). On average, agricultural or developed lands accounted for 43% of the lands within 1 km of the plots (Table 4).

The riparian vegetation within most survey plots also was somewhat altered in its composition and structure. In general, the tree layer was discontinuous and averaged only 46% cover, and the shrub layer also had a comparable cover (Table 4). Willows and Fremont's cottonwood accounted for just 16% of tree cover, and oak species (primarily interior live oak and valley oak) accounted for 26%. Non-native species occupied little of this tree layer (5%), but Northern California black walnut, a species absent from this region 150 years ago, accounted for an additional 4% of total tree cover. In the shrub layer, the non-native Himalayan blackberry accounted for over half of all shrub cover.

Table 3. Presence of Infrastructure and Evidence of Disturbance in Plots[1]

Attribute	Total *N = 47*	Placer County Plots *N = 23*	Plots Outside Placer Co. *N = 24*
Presence of Bank Protection	4	5	4
Levee or Berm	15	4	25
Road in Plot	46	50	42
Stream Incision	61	55	67
Evidence of Overbank Flow	57	41	71

Notes:

1 *N* = 47.

2 Riparian width, and tree, shrub and herb covers are ground-based measurements and land-cover variables are geographic information systems (GIS)–based.

3 SD = standard deviation.

4 Sample was stratified by anticipated riparian width, thus these width statistics are not representative of riparian vegetation width in the Sacramento Valley (e.g., the Valley's mean width is narrower).

The six relatively unaltered plots (i.e., no infrastructure in plot and no agricultural or developed land within 250 m) varied widely in their vegetation structure and species composition. The width of their riparian vegetation ranged from 8 m to 200 m. In the tree layer, the cover of oak species ranged from 0 to 78% and the cover of willows and cottonwood from 0 to 30%. The shrub layer varied from over 80% Himalayan blackberry (*Rubus discolor*) to a sparse cover (5%) of shrubs and tree saplings. With the exception of tree cover, these relatively unaltered plots bracketed the range of conditions observed in other plots that were more altered. None of the unaltered plots had low tree covers (range 40-80%); in contrast, 49% of other plots had tree covers below 40%.

There were relatively few strong relationships among site attributes (Table 5); however, suggestive positive relationships existed among riparian vegetation width with tree and shrub cover. Otherwise, most negative relationships were between variables that are inversely related by definition (e.g., land cover proportion) and most positive relationships were between variables that represented the same land cover category at different scales (e.g., developed land within 250 m, 1 km and 5 km).

Data collected at the 12 intensive data collection sites varied in their value for assessing riparian habitats. At these sties, almost no amphibians or reptiles were found beneath the cover boards. The results of the small mammal trapping varied substantially among sites (Table 6, Appendix B), and they did not correspond closely to the results of surveys for other taxonomic groups. However, conducting area searches for vertebrates on multiple dates resulted in more complete species lists (i.e., greater species richness) compared to lists based on a single area search, and species richness estimates based on multiple surveys had stronger relationships to site attributes than single survey estimates (Tables 7 and 8, Figure 1).

Three of the relatively unaltered plots were intensive data collection sites, and at these plots, results were similar to those at more altered sites, with the exception of small mammal density and the number of potential nesting bird species. The total number of small mammals trapped at the unaltered sites averaged 32 ± 4 (mean $\pm$ standard error) versus 3 ± 1 at the more altered plots. The number of potential nesting bird species at the unaltered sites averaged 3.3 ± 0.3 versus 1.1 ± 0.4 at the other plots (Table 6).

Mammal Spp (4 Surveys)	12	2.3	1.2	1–4
Amphibian and Reptile Spp (1 Survey)	47	0.8	1.0	0–3
Amphibian and Reptile Spp (4 Surveys)	12	2.7	1.1	1–4

Notes:

1 Numbers in table are numbers of species observed per plot, except for small mammal density, which is number of individuals per plot.

2 Abbreviations: N = number of plots, SD = standard deviation, Spp = species.

3 Number of individuals per unit area (not number of species).

With the exception of relationships between surrounding land cover types and vertebrate species richness, our results did not strongly support our initial research hypotheses. In most cases, the species richness of riparian-associated birds was not strongly related to the species richness of other animal groups, though two relationships were significant (Table 7, Figure 2). There was a significant relationship between riparian-associated birds and mammal species (4 surveys, $df = 10$, $r = 0.71$, $p < 0.05$ and < 0.01 without Bonferroni adjustment). There were also significant relationships between potentially resident riparian-associated birds and amphibians and reptiles (based on 4 surveys, $df = 10$, $r = 0.76$, $p < 0.01$, without Bonferroni adjustment $p < 0.005$).

Species richness did not increase significantly with the width of riparian vegetation for any animal group. Correlation coefficients between species groups and riparian width generally were all below 0.40 (Table 8). Results for riparian-associated birds (based on 1 survey) suggested a positive relationship with riparian width ($df = 45$, $r = 0.35$, $p < 0.07$ and < 0.009 without Bonferroni adjustment; Table 8, Figure 3). This could be considered evidence of a significant relationship. However, for the multiple survey plots, there was not a relationship between the number of riparian-associated bird species and riparian width ($df = 10$, $r = 0.16$, $p > 0.25$ without Bonferroni adjustment; Figure 3). Similarly, the species richness of other animal groups had no significant or suggestive positive relationships with riparian width. Riparian width was initially included in four regression models (Table 9), although, in one case (riparian-associated birds based on 1 survey), width was not included in the final model.

In general, species richness of the animal groups had no significant or suggestive relationships with the area of riparian vegetation, and only weak relationships with tree or shrub cover (Table 8). However, riparian-associated birds,, based on 1 survey, had a highly significant relationship with tree cover ($df = 45$, $r = 0.49$, $p < 0.004$ and $p < 0.0005$ without Bonferroni adjustment; Figure 3). The species richness of other animal groups did not have significant or suggestive relationships with riparian woody plant cover.

For the plots receiving multiple surveys, significant correlations existed between vertebrate species richness and surrounding land cover. For these data, nearly half the correlation coefficients were between 0.50 and 0.87, and 14 of these were significant or suggestive (Table 8).

The species richness of riparian-associated birds was significantly related to the extent of surrounding natural and agricultural lands. Riparian-associated birds (based on 4 surveys) had suggestive relationships with percent of surrounding land in natural vegetation within 250 m, 1 km and 5 km ($r = 0.67$–0.73, $p < 0.22$-0.09 and $p < 0.009$–0.004 without Bonferroni adjustment). If the count of riparian-associated bird species at each plot were restricted to just potential nesting species, the relationships to adjacent land cover were stronger. For this set of observed riparian-associated bird species, correlations with agricultural and natural land cover within 250 m had coefficients of -0.84 and 0.82, respectively, indicating strong relationships with surrounding land cover (p values < 0.01-0.02 and < 0.0005 without Bonferroni adjustment). This group also had suggestive relationships to natural and agricultural land cover at other scales (Table 8). Furthermore, no breeding or nesting behaviors were observed for riparian-associated birds at the sites with higher portions of the surrounding area in agricultural land at 250 m (Figure 4).

Similarly, in the multiple survey data sets, the species richness of amphibians, reptiles and mammals was related to surrounding land-cover within 250 m to 5 km. Species richness of amphibians and reptiles had a significant relationship with the portion of the surrounding area in agricultural land for the areas within 1 km and 5 km ($r = -0.78$ and -0.85, respectively, $p < 0.04$ and 0.01, respectively, and p values < 0.002 and < 0.0005 without Bonferroni adjustment). Similarly, species richness of mammals had a significant negative correlation with developed land cover within 250 m and 1 km ($r = -0.82$ and -0.87, respectively, $p < 0.02$ and 0.01, and p values < 0.001 and 0.0005 without Bonferroni adjustment), and suggestive correlations to natural land cover (Table 8).

Although some of the relationships between vertebrate species richness and surrounding land cover were considered just suggestive in the context of this analysis's numerous hypothesis tests, each of these relationships accounted for a moderate portion of the variability among the multiple survey plots in the species richness of a vertebrate group.

Combinations of variables did not produce substantially stronger models for predicting species richness than did single variables. For the individual

[1] $n = 47$

Figure 3. Relationship of Species Richness of Riparian-Associated Birds and Selected Site Attributes[1]

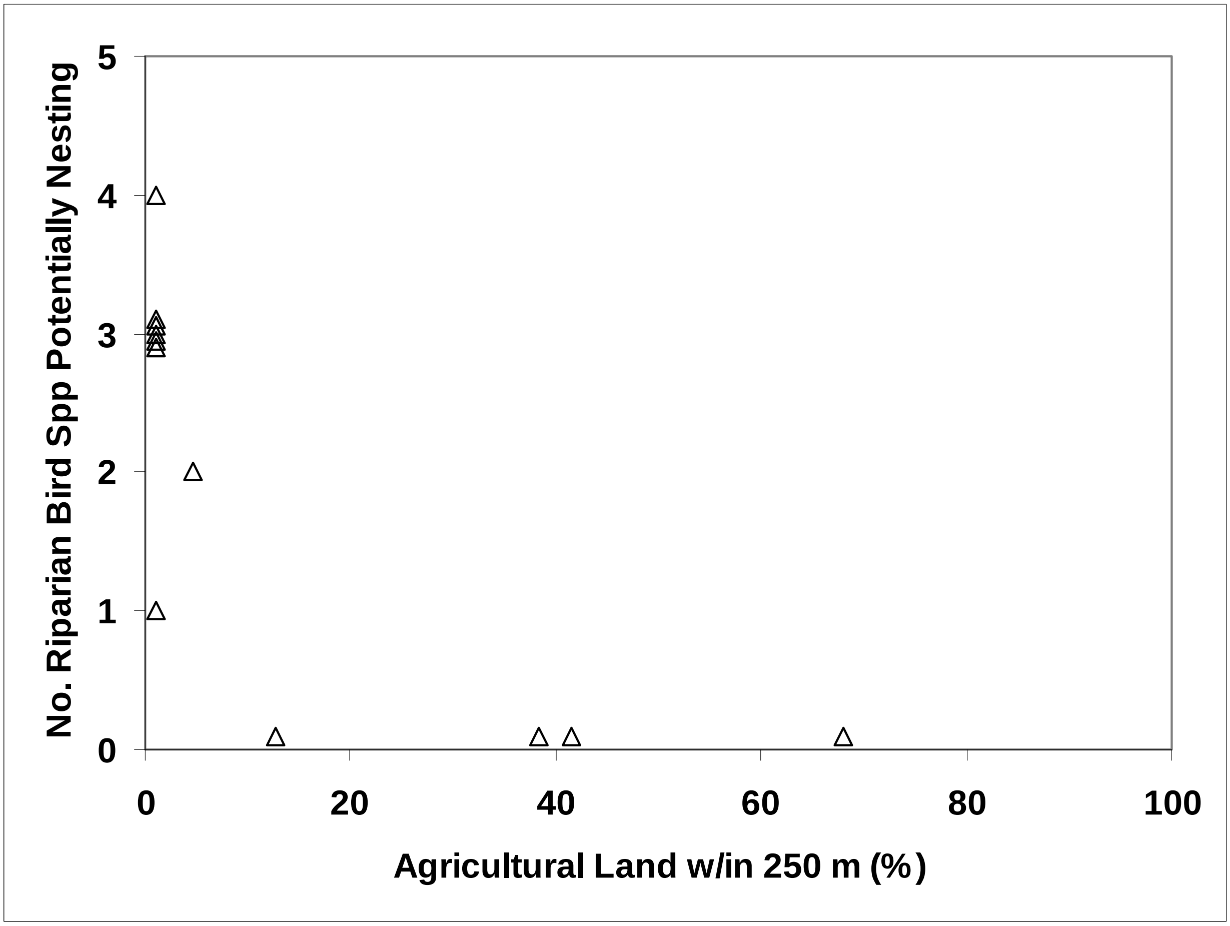

Figure 4. Relationship Between Number of Riparian-Associated Bird Species Potentially Nesting at a Site and Adjacent Agricultural Land

taxonomic groups, simple linear and stepwise multiple regression produced models with *p* values between < 0.0001 and 0.064 (Table 9). For all vertebrate species, the models consisted of one or two variables and almost all independent variables represented surrounding land cover. Only three of these models had R^2 values > 0.5: riparian-associated birds (4-surveys), riparian-associated birds potentially nesting (4 surveys) and amphibians and reptiles (4 surveys). The amphibian and reptile model was based only on the percent of area within 5 km that was in agricultural land. The model for potential nesting riparian-associated birds was based on two land cover variables, but just one of these (natural vegetation within 250 m) accounted for 86 % of the variability explained by the model. For riparian-associated birds (all observed during 4 surveys regardless of behavior), the regression model based on two variables was substantially stronger than for any one variable ($R^2 = 0.63$).

Discussion

The results of this study must be interpreted cautiously due to limitations of the study's overall sample size, attributes of available sites and chosen methodologies. Nonetheless, the results have implications for assessment methodologies, development of a FAM, and for riparian setbacks. These implications are discussed in the following sections.

Implications for Biological Site Surveys to Assess Riparian Biodiversity

These results indicated that data from multiple site surveys for vertebrates provide a much stronger basis for assessing a riparian area than data from a single site visit. Not only did data from four site surveys document more species than a single survey of those sites, but the results of single and multiple surveys were not highly correlated with each other. Overall, multiple site surveys provide a much more consistent basis for evaluating the habitat value of riparian sites.

These results also indicate that non-destructive area searches for mammals, amphibians, and reptiles were not an effective survey technique, even with the placement of cover boards. Overall, few species were observed during these area searches, usually less than one amphibian or reptile species during a single survey. Though few amphibian or reptile species may have been present, the results still demonstrate that a single non-destructive area search is not an effective means of inventorying the mammal, amphibian, and reptile species using a site. In most plots surveyed multiple times, additional species were observed, indicating that during a single survey most species using a site were not detected. No amphibian or reptiles species was observed beneath any of the 240 cover boards set out and checked 4–6 times during this study. However, cover boards may be more effective is used during late winter-early spring rainy season, when conditions beneath them would be more favorable for amphibians and reptiles, and possibly if constructed using thicker materials that provided better insulation from higher temperatures.

Implications for a FAM

Overall, our results indicate that, for the smaller streams and rivers of the Sacramento Valley, developing a single model that *precisely* quantifies *overall* habitat functions on the basis of readily measured site attributes is not possible, particularly on the basis of available information. However, the results do show that some readily measured site attributes are related to the species richness of particular taxonomic groups. For particular species, guilds, or taxonomic groups, this indicates that useful assessment criteria based on readily measured site attributes could be developed as shown in the examples in Table 10.

In this study, the species richness of different groups (particularly between vertebrates and invertebrates) was not related, and species groups often differed in their relationships to plot attributes. In general, species differ in their biology and thus their habitat requirements, particularly across major taxonomic groups such as vascular plants, butterflies and mammals. Therefore, numerous specific site attributes such as disturbance history, vegetation structure, and presence of host plants, refugia, or rock outcrops affect these species groups differently, and many of these attributes are themselves only loosely related to the landscape variables that are most useful for a cost-effective FAM (e.g., surrounding land use, area and width of riparian vegetation). Thus, models, or assessment criteria, that focus on individual species or guilds will likely provide more useful assessments of a site's habitat value than a model that attempts to quantify habitat value for all species combined (Stein et al. 2000; Smith 2000; Bryce et al. 2002).

In this study, the vertebrate groups had relationships to site attributes, and thus for particular vertebrate taxonomic groups, guilds or species effective assessment criteria based on readily measured site attributes probably could be developed through additional studies. In data from multiple site visits, which were most effective at documenting species' presence, relationships between species richness and surrounding land use were important.

Unfortunately, due to their sample size and the types of data collected, these data sets have substantial limitations. They consist of only twelve plots, and they contain few or no replicates of some important types of sites (e.g., wide riparian corridors in urban areas). They also were scattered over a wide and heterogeneous geographic area. Furthermore, they contain little information on abundance and no information on rates of growth, survival or reproduction. Thus, while these data indicate the importance of surrounding land uses, and other readily measured site attributes, additional studies with larger sample sizes, and collecting other types of ecological data (e.g., density, survival or reproduction), are necessary for defining assessment criteria that precisely quantify habitat values under different combinations of site attributes. We consider such studies important next steps for the conservation planning process.

Table 10. Evaluation of Habitat Functions by Representative Functional Assessment Methods

Assessment	Terrestrial Habitat Functions	Variables used to Assess Habitat Function	Tested[1]
Spatial Wetland Assessment for Management and Planning, SWAMP (Sutter 2001)	Terrestrial wildlife habitat	Area of interior habitat Heterogeneity of vegetation Presence of surface water	No
Assessment of riverine wetlands in Washington State (Hruby et al. 1999)	Bird, Mammal, Amphibian Habitat	Density and condition of snags Presence of special features Evidence of disturbance on adjacent land Interspersion of vegetation types	No
Hydrogeomorphic assessment (HGM) of riverine floodplains in the Northern Rocky Mountains (Hauer et al. 2002)	Characteristic vertebrate habitats	Cover in herb and shrub layers and of native species Tree density Inundation frequency Connectivity of vegetation types	No
Suggested revisions to BLM's Proper Functioning Condition assessment procedure (Stevens et al. 2002)	Fish and wildlife habitat	Canopy connectivity Vegetation patch density Fluvial landform diversity	No
Southern California Riparian Model (Stein et al. 2000)[2]	Condition units[2]	Cover of native plants Percent invasive species Vegetation structural diversity Riparian vegetation continuity Adjacent land cover	No
Bird Integrity Index (Bryce et al. 2002)	Overall riparian integrity including overall habitat integrity	Number or proportion of bird species (or of individuals) in selected guilds	Yes
Tidal freshwater wetlands along Hudson River (Findley et al. 2002)	Breeding Bird, Muskrat and Waterfowl Habitat[3]	Cover or stem density of plant species Soil texture	No[3]
Wetland Assessment, WEA, for San Francisco Bay Region (Breaux and Martindale 2003)	Wildlife Utilization Rating	Guidelines for professional judgment	No
San Diego Creek Assessment (Smith 2000)	Riparian habitat integrity	Native riparian vegetation area Riparian corridor continuity Adjacent land use/land cover	No
Indicator Value Assessment, IVA (Hruby et al. 1995)	General waterfowl, General wildlife	Numerous (>60 indicators)	No
Wetland Habitat Assessment Technique, HAT (Cable et al. 1989)	Habitat quality	Bird species presence Wetland area	No

Notes:

1 Tested by comparison to direct measurements of species presence, abundance or demography. For assessments that used direct measures of animal species group (e.g., birds) presence to assess overall site condition or habitat quality, testing requires comparison to direct measurements of other animal groups.

2 Habitat function incorporated into overall rating (i.e., condition units), and only habitat variables are listed in this table.

3 This study also included fish and aquatic invertebrate habitat functions that were tested by comparison to direct measurements.

As one of these next steps, PRBO's point count dataset provides an excellent opportunity to evaluate relationships between the abundance (i.e., number of individuals) of riparian-associated bird species and riparian width and surrounding land cover. Point count surveys are designed to record the relative abundance of individual species, and PRBO has conducted these surveys for over a thousand locations over multiple years. Their analysis would require the calculation of GIS-based landscape metrics (comparable to the surrounding land cover variables used in this study) and an aerial photo-based interpretation of riparian width. Nonetheless, the analysis of existing PRBO point count data would be a cost-effective means to rigorously analyze relationships between the abundance of species and riparian width and surrounding land cover.

Because of the differences among species groups, and the limitations of current knowledge, a FAM for western Placer County that calculates a single score for a riparian area's habitat functions should be considered only a very general indicator of the overall provision of habitat functions. Such a score should be based on a limited number of variables, preferably just one or two variables that are broadly related to most habitat values and the processes sustaining them (e.g., proportion of surroundings in natural vegetation, hydraulic connectivity). This would limit inaccuracies caused by the operations and coefficients selected to combine variables, and would maintain a mechanistic basis for the assessment.

Implications for Riparian Setbacks

Though width of riparian vegetation was not strongly related to species richness, as measured by these measures, this result should not be interpreted as evidence that the width of a riparian setback is not an important consideration for habitat conservation. This study's sample size, particularly for the multiple survey sites, was small and spread over a large geographic area. Thus, it is likely that only effects of larger magnitude would have been identified and locally important effects would not have been detected without a larger sample size. Width may be important for some species, but these species might be few in number or absent from our data sets. Because all but a few plots represented landscapes substantially altered by human use, most species sensitive to these alterations (including a reduction in riparian width) may no longer be present at any of the study sites. For example, Western Yellow-billed Cuckoo is such a species (Greco et al. 2002) and was not detected at any of the 47 plots during our surveys.

Riparian setbacks would include both riparian and other natural vegetation, and their width would be directly related to the extent of adjacent natural, agricultural and developed land cover; and the proportions of surrounding land-cover types were related to species richness in this study's results. Furthermore, other studies, have shown relationships between the width of riparian vegetation and the presence of riparian-associated animals (Greco et al. 2002).

This study's results indicated that there are important relationships between adjacent land use within 250 m–5 km and the biodiversity of riparian corridors in the Sacramento Valley. These relationships are consistent with studies of riparian habitat elsewhere (Findlay and Houlahan 1996; Forman and Alexander 1998; Bryce et al. 2002; Miller et al. 2003; Semlitsch and Bodie 2003) and with our understanding of factors known to affect riparian species in the Sacramento Valley, such as the availability of upland habitats also used by many of these species. Thus, riparian setbacks should consider both the condition and management of riparian vegetation and the buffer between this vegetation and adjacent developed and agricultural lands. Also, the results suggest that riparian setbacks may not be able to prevent all adverse effects of surrounding land uses on riparian biodiversity, and thus that other conservation measures may be necessary as well. These conservations measures will be discussed in the report providing guidance for riparian setbacks.

However, the results of this study are not by themselves a sufficient basis for recommending setback or buffer widths. For this reason, our report providing guidance for riparian setbacks (Task 5 of the Riparian Ecosystem Assessment), will consider these results together with other available data, and a review of the scientific literature regarding the use of adjacent land by riparian species and the influences of adjacent land uses on those species.

Acknowledgements

We would like to acknowledge the guidance provided by Placer County Planning Department staff (M. Batteate and L. Clark) and by the members of the County's technical advisory Committee, and the collaboration of the Point Reyes Bird Observatory. For their personal assistance, we also thank G. Ballard, P. Cylinder, C. Hicks, K. Keller, W. Kohn, D. Leslie, S. Myers, S. Parsons, G. Platenkamp, J. Robins, E. Routt, W. Shaul, D. Stralberg, E. West, and M. Widdowson.

Appendix A
RAP Forms

Protocol for Description of Riparian Ecosystem Assessment Plots

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the site description and any other RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

LOCATING THE PLOT

Proceed to the pre-determined coordinates for the plot center point. Centered on this point, the plot edge ds 100 m along the stream bank edge of the riparian zone (50 m up and 50 m down stream), and then extends 100 m inland (away from the stream bank). In most cases, the actual center of the located plot will differ from the pre-determined coordinates used to locate the plot. Therefore, once the plot boundaries have been determined, the actual coordinates for the plot center point are determined and recorded on the data form (see below).

RIPARIAN RAP DATA FORM

The intent of the RAP data form is to facilitate the collection of field data at selected plots rapidly and accurately. At each plot record the required data in each of the following data fields:

Location

- Provide the River/Creek name and number the plot (e.g., Deer Creek #1).
- Provide the survey date(s) and names of surveyors.
- Use the GPS unit to determine coordinates for the center point of each plot; and record the lat/long on the form. (Elevation will be determined from USGS topographic map and recorded on the form afterwards.)

- Take photographs facing North, East, South, and West, and of a representative view of the riparian corridor. Record their numbers on the form.

Environmental Description

This provides a brief description of the general slope exposure and steepness of the riparian plot that is sampled. If slope varies within the plot, record the slope across the plot as a whole (i.e., from the stream-side to the inland side of the plot).

ADJACENT LAND USES AND IMPACTS

***Developed Non-industrial Land Uses* -** Record the extent of adjacent residential and suburban development with 250 m of the center of the survey plot both by noting the percentage of area covered by these land uses and recording the number of development units (du) observed, including barns and other out buildings.

Agricultural Land Uses – Record agricultural development within 250 m of the center of the plot both by recording the percentage of area covered by agricultural land uses, and by noting the general agricultural type(s) observed.

Industrial Land Uses – Record industrial development within 250 m of the center of the plot both by recording the percentage of area covered by industrial land uses and by noting the general type of industrial uses observed.

Impact Types – In the table provided, for both the riparian and non-riparian portions of the plot, record the presence of the following impacts: brush removal, tree cutting, roadedness, grazing, and trash dumping. The adjacent area extends 250 m from the center of the plot. If the adjacent area is not in natural vegetation, do not record brush cutting, tree cutting, or trash dumping as occurring in the adjacent area. In documenting roadedness, all roads, including dirt and gravel, and other impervious or heavily compacted surfaces are included in this type of impact. For the other category, specify the impact type.

Channel Condition – Indicate whether bank protection has been used in the channel adjacent to the plot, and whether the channel shows evidence of incision. Note whether levees are present at or near the site that may confine the extent of potential riparian habitat areas, and indicate whether there is evidence of overland flow on the plot. Also, indicate the distance to the nearest road (paved, gravel or dirt).

ADDITIONAL COMMENTS

Add any additional comments on site access or interpretation, including management of creeks (e.g., recent revegetation or clearing, channelization, herbicide use, etc.). Also, if aerial photos are available and vegetation has changed since the photograph was taken, this should be noted. Add these additional comments, as necessary, at the bottom of the form.

VEGETATION DESCRIPTION

- In the box provided, enter the Habitat Type(s) using the appropriate Placer County WHR codes (Attachment 2).
- Estimated width of the riparian vegetation. Estimate the width of the riparian stand using a range finder at the center and both ends of each plot and record these widths on the data form.
- Record the surrounding habitat types using the Placer County WHR codes.
- Estimate the total size of the stand from aerial photos and ground inspection, and record its approximate length and continuity, as indicated on the form.
- Record estimates of total absolute cover (expressed as a percentage) of the tree, shrub, and herbaceous layers, and estimate the total extent of unvegetated ground (i.e., bare ground).

- Estimate the total snag density as high (> 20 per hectare), moderate (10-19 ha^{-1}), low (< 10 ha^{-1}), or absent.
- Check the appropriate habitat stage category for that represents the size of the trees dominating the tree layer.
- In the table provided, based on a visual estimate, record the scientific name and check the appropriate category for absolute cover for each woody species in the tree layer (> 3 m), and in the shrub layer (0.5-3 m).

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.
- Surveyors should review each other's completed forms for completeness and accuracy in the field.
- From topographic maps, add plot elevations to the RAP data form.
- Photocopy all your field forms. File the copes in the file cabinet in Ted's office and the originals in the Placer Legacy office.
- Download the digital photographs into the P drive folder and rename with the site, point number and orientation (e.g., Thomes 7-1 N, Thomes 7-1 E etc.).
- Download the site coordinates from the GPS into the P drive folder.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

URF Rural-residential Forested (0.1-1.0 unit/acre plus 70-90% canopy cover of large trees)
UP Urban Parks (includes isolated city parks: playgrounds, grass fields, etc)
UG Golf Courses
UT Urban riparian (includes internal riparian areas such as greenbelts, most often surrounded by residential/urban development)
UF Urban woodland (includes city parks with predominate woodland type vegetation and windbreaks with mostly non-native trees)
UW Urban wetland (includes vernal pools, seasonal wetlands, and emergent marshes surrounded by urban uses)

Small-Patch Ecosystems

XW Springs and Seeps
XP Stock Ponds (less than 1 acre)
XL Landscape and Golf Course Ponds (less than 1 acre)

Special Geologic Formations and Soils

XG Gabbrodiorite Soils
XS Serpentine Soils
MR Mehrten Formation Soils

BIRD AREA SEARCH PROTOCOL

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

LOCATING THE PLOT

Proceed to the coordinates for the center point of the 100 m by 100 m plot. Centered on this point, the plot edge is 100 m along the stream bank edge of the riparian zone (50 m up and 50 m down stream), and then extends 100 m inland (away from the stream bank).

CONDUCTING THE AREA SEARCH

The area search involves conducting a census of the entire1 ha plot (100 m X 100 m) and recording all bird species detected there. Please use the PRBO area search form to record data. Each area search plot is covered in approximately 1 hour to provide comparable search time at each plot. Typically, at least 3 plots should be covered in a single morning.

Begin the area search by filling out the observer and census information at the top of the PRBO AREA SEARCH FORM. Complete the weather information, and record the air temperature, % cloud cover (% of sky covered in clouds), and approximate wind speed using the attached Beaufort wind scale.

During the census, carefully record the name of each species seen, heard, or for which tracks or scat was observed. Please use the species' common name (not 4-letter codes) to avoid later confusion. For each individual of each species, record a single letter (S=song, V=visual, C=call), in the order of priority explained in the code key. You should change the data (i.e. from a call to a song) if a higher priority observation later occurs for that individual. Also, record breeding and nesting behavior. Recording other special behaviors (such as food carries, flocking, displaying), is strongly recommended but not required; there are respective columns on the form for these observations, following breeding bird atlas methodology. Other species observed off the plot or flying over may be recorded under Notes and Flyovers or on a separate sheet of paper.

In recording species on the data form, note whether the species was observed in the riparian or non-riparian portions of the plot.

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.
- Surveyors should review each other's completed forms for completeness and accuracy in the field.
- Photocopy all your field forms. File the copes in the file cabinet in Ted's office and the originals in the Placer Legacy office.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

Beaufort Wind Scale

Used to guage wind speed using observations of the winds effects on trees and other objects. Often used in monitoring projects because it doesn't require fancy equipment.

Format: Beaufort Number * Wind Speed in Miles/hour(Km/hour) *** Description**

0 *** <1 (<1.6)***__Calm:__ Still: Smoke will rise vertically.

1***1-3(1.6-4.8)*** **Light Air:** Rising smoke drifts, weather vane is inactive.

2***4-7(6.4-11.3)***__Light Breeze:__ Leaves rustle, can feel wind on your face, weather vane is inactive.

3***8-12(12.9-19.3)***__Gentle Breeze:__ Leaves and twigs move around. Light weight flags extend.

4***13-18 (20.9-29.0)***__Moderate Breeze:__ Moves thin branches, raises dust and paper.

5***19-24 (30.6-38.6)***__Fresh Breeze:__ Moves trees sway.

6***25-31(40.2-50.0) *****Strong Breeze:** Large tree branches move, open wires (such as telegraph wires) begin to "whistle", umbrellas are difficult to keep under control.

7***32-38 (51.5-61.2)***__Moderate Gale:__ Large trees begin to sway, noticeably difficult to walk.

8***39-46(62.8-74.0)***__Fresh Gale:__ Twigs and small branches are broken from trees, walking into the wind is very difficult.

9***47-54(75.6-86.9)***__Strong Gale:__ Slight damage occurs to buildings, shingles are blown off of roofs.

10***55-63 (88.5-101.4)***__Whole Gale:__ Large trees are uprooted, building damage is considerable.

11***64-72 (103.0-115.9)***__Storm:__ Extensive widespread damage. These typically occur only at sea, and rarely inland.

12***>73 (>115.9)***__Hurricane:__ Extreme destruction.

NOTE: The Beaufort number is also referred to as a "Force" number, for example,
"Force 10 Gale".

* To calculate knots, divide miles/hour by 1.15.

www.prbo.org

prbo

Be sure you have the following:

- binoculars
- watch which indicates seconds
- at least 2 pens
- field notebook
- sufficient blank data forms
- clipboard
- rubber bands (for holding forms on clipboard)

Depending on the route, census type, and your experience level, you may also need:

- directions and maps
- GPS unit & extra batteries
- cell phone or radio
- range finder
- field guide
- water and snacks

Counts begin approximately 15 minutes after local sunrise and should be completed within 3-4 hours, generally by 10AM.

We recommend 2-3 visits per season (e.g., twice in May and once in June). Visits should be at least 10-15 days apart. Timing of the field season will vary by location, but should cover the local breeding season with as little overlap with migration or dispersal as possible.

When possible, the order in which points are surveyed should vary between visits. Ideally, observers should also vary among visits.

Do not conduct surveys during weather conditions that likely reduce detectability (e.g., high winds or rain). If conditions change for the worse while doing a count, remaining points can be completed <7 days from the first day, but this should be avoided as much as possible.

Approach the point with as little disturbance to the birds as possible, and begin your count as soon as you are oriented and are confident you can estimate distances accurately (less than 1 minute).

PRBO point counts are 5 minutes duration at each point. Record the time the survey begins at each point using the 24-hour clock. If something interferes with your ability to detect birds during the 5-minute count, stop the count until

PRBO Conservation Science
4990 Shoreline Highway
Stinson Beach, CA 94970
415-868-1221
www.prbo.org

prbo

the disturbance has passed and start over. Cross out the interrupted data and note what happened on your form.

Every species detected at a point is recorded, regardless of how far from the observer. Use the standardized banding lab 4-letter abbreviation for species codes (http://www.pwrc.usgs.gov/bbl/manual/bandsize.htm) and follow the naming conventions maintained by the American Ornithologists Union (http://www.aou.org/aou/birdlist.html). For unknown species, record "XXXX." For unknown members of various families, use "XX" plus two letters to signify the family – "XXHU" for unidentified hummingbird, for example. You can follow birds after the completion of a point in order to verify identification. If no birds are detected at a point, write "No birds detected" on your form. We recommend keeping a list of all species detected between points (i.e., not during the 5 minute counts) on the back of your form.

For each individual detected we record the distance to the detection and the behavior that alerted us to the individuals' presence. Also, for each species we record any indications of breeding status. Make every effort to avoid double counting individuals detected at a single point. However, if an individual is known or thought to have been counted at a previous point, make a note of it, but record its presence at the current point anyway. No attracting devices, recordings, or "pishing" should be used.

Distance: All point counts involve recording distance to detections at some level of resolution. Depending on project, we use either 50m fixed-radius counts, or Variable Circular Plots (VCP), in which the distance to each detection is recorded to the nearest 10m (though this distance may vary by project and habitat type – consult project leader). Both methods also specify whether or not detections were beyond 100m.

Note: Fifty m radius counts may not provide sufficient data for calculating population density or trends for some species or habitats where the use of VCP's may improve estimates. We recommend the use of range finders and extensive training for either method, but especially for VCP. VCP data should always be taken in a way that is transferable to 50m format.

The distance recorded is the distance from the point to the first location an individual was observed, regardless of its behavior. If the bird subsequently moves, *do not change the original distance recorded*. If a bird is flying (but not "flying over" – see below), or perched high in a tree, the distance recorded is to the point at which a plumb line would hit the ground if hung from the point at which the bird was first observed. This distance should be measured as

PRBO Conservation Science
4990 Shoreline Highway
Stinson Beach, CA 94970
415-868-1221
www.prbo.org

prbo

though a tape were laid across the ground, that is, including any intervening topographic features.

A bird flushed from within 10m of the point when you arrive should be included in the count. Birds that are flushed from farther away should be noted on the back of the form if they are species that didn't occur during the count.

We record the behavioral cue that alerted us to the presence of the individual - generally "S" for song, "V" for visual, or "C" for call (“D” for drumming woodpecker, “H” for humming hummingbird). If a bird sings after it has been detected via a different cue, this is indicated in the data, but the initial detection cue is preserved. Circle the original detection cue ("V" or "C") to note that a bird was singing subsequent to its initial detection, but otherwise, no changes in behavior are noted. Juvenile birds are recorded as “J”s regardless of their behavior, and are not included in most analyses.

Birds that are flying over but not using the habitat on the study area are recorded in the fly-over column. Birds flying below canopy level, flying from one perch to another, or actively foraging on or above the study area are recorded as described in the previous paragraphs.

Breeding status: We record any potential indications of breeding if noted for species at each point as follows:

- CO – copulation
- DI – territorial display.
- DD – distraction display
- FC – food carry
- FL – fledglings
- FS – fecal sac carry
- MC – material carry
- NF – nest found
- PA – pair

Riparian Ecosystem Assessment Mammal Area Search Protocol

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

LOCATING THE PLOT

Proceed to the coordinates for the center point of the 100 m by 100 m plot. Centered on this point, the plot edge is 100 m along the stream bank edge of the riparian zone (50 m up and 50 m down stream), and then extends 100 m inland (away from the stream bank).

SEARCHING FOR MAMMALS

Area searches are conducted for approximately 1 hour to ensure comparable search effort on each plot. Begin the area search by entering the observer, date, time and site information at the top of the *Mammal Area Search* form. During the census, carefully record the name of each species seen or heard. Please use the species' common name (not 4-letter codes) to avoid later confusion. The area search involves walking throughout the entire (100 m by 100 m) plot.

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.
- Surveyors should review each other's completed forms for completeness and accuracy in the field.

- Photocopy all your field forms. File the copes in the file cabinet in Ted’s office and the originals in the Placer Legacy office.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

Riparian Ecosystem Assessment Amphibian & Reptile Search Protocol

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

Where data on amphibians and reptiles will be collected, cover boards will be placed out during the first visit to the site, and will be checked during the next visit (at least a week later).

LOCATING COVER BOARDS WITHIN THE PLOT

Proceed to the coordinates for the center point of the 100 m by 100 m plot. Centered on this point, the plot edge is 100 m along the stream bank edge of the riparian zone (50 m up and 50 m down stream), and then extends 100 m inland (away from the stream bank). Locate the first 100 m line of cover boards along the length of the stream bank side of the plot. Place 10 cover boards, evenly spaced apart, along this first line. Place an additional 10 cover boards along a second 100 m line 10 m in from the stream bank side of the plot and parallel to the first line of cover boards.

SEARCHING FOR AMPHIBIANS AND REPTILES

Area searches are conducted for approximately 1 hour to ensure comparable search effort on each plot. (If area searches deviate from the 1 hour duration, note this in the “Additional Comments” section of the data form.) Begin the area search by entering the observer, date, time and site information at the top of the *Amphibian and Reptile Data Collection* form. During the census, carefully record the name of each species seen or heard. Please use the species' common name (not 4-letter codes) to avoid later confusion. The area search involves walking throughout the entire (100 m by 100 m) plot and also checking under all cover boards. In checking cover boards, quickly lift each cover board and identify species present. Only handle amphibians and reptiles if you have a DFG permit and you cannot identify them. Most species should be identifiable without handling them. After it has been checked, replace each board in its original position. Please collect all cover boards and remove any flagging after the final plot survey.

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.
- Surveyors should review each other's completed forms for completeness and accuracy in the field.
- Photocopy all your field forms. File the copes in the file cabinet in Ted's office and the originals in the Placer Legacy office.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

Riparian Ecosystem Assessment Butterfly Search Protocol

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

Where data on amphibians and reptiles will be collected, cover boards will be placed out during the first visit to the site, and will be checked during the next visit (at least a week later).

SEARCHING FOR BUTERFLIES

All butterfly area searches must take place between 9 AM and 4 PM because of the daily flight patterns of butterflies. Area searches are conducted for approximately 1 hour to ensure comparable search effort on each plot. (If area searches deviate from the 1 hour duration, note why in the “Additional Comments” section of the data form.) Begin the area search by entering the observer and site information at the top of the *Butterfly Area Search* form. The area search involves walking throughout the entire (100 m by 100 m) plot. During the census, carefully record the name of each species seen. Please use the species’ scientific name (not 4-letter codes) to avoid later confusion. Indicate the relative abundance of each species in the *General Abundance* column of the data form using the following scale: Rare (1 individual), Uncommon (2-5 individuals), Common (5-10 individuals), Abundant (> 10 individuals).

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.

- Surveyors should review each other's completed forms for completeness and accuracy in the field.
- Photocopy all your field forms. File the copes in the file cabinet in Ted's office and the originals in the Placer Legacy office.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

Riparian Ecosystem Assessment Small Mammal Trapping Protocol

INTRODUCTION

These protocols provide a guide to assist the survey team in obtaining the required information as efficiently as possible. Minor modifications to these protocols may be necessary depending on access constraints and time available to complete the surveys. All RAP surveys will be done at riparian sites that PRBO has surveyed previously and at Placer County riparian sites where permission is granted from the landowners. Assume that all land is private and do not trespass if you are uncertain about the land ownership. Also, avoid stopping in front of residences and generally be discrete about displaying maps, cameras, and clipboards. Be careful about pulling off roads and do not violate any traffic laws to sample a riparian plot or observe a species. Always leave gates exactly as you found them. Also, for Placer County sites, it is important that all requirements specified by the landowner are followed. These requirements are attached to the directions, map, and photograph for each plot in Placer County.

PREFIELD TASKS

Prior to performing the field surveys, please review the following materials that will be provided in the field packets:

- Road maps and maps of the individual streams showing roads and access points so that survey routes can be planned and surveyed efficiently;
- PRBO field notes giving directions to individual sites, vegetation descriptions, and bird species lists for survey plots;
- Aerial photographs of individual creeks and rivers (as available).

Plan your route to the riparian sites and consult the field checklist to ensure that you have gathered all the necessary equipment to complete the RAP survey work you will be conducting (an equipment and contact list is included as Attachment 1).

LOCATING TRAPS WITHIN THE PLOT

Proceed to the coordinates for the center point of the 100 m by 100 m plot. Centered on this point, the plot edge is 100 m along the stream bank edge of the riparian zone (50 m up and 50 m down stream), and then extends 100 m inland (away from the stream bank). Locate the first 100 m line of traps along the length of the stream bank side of the plot. Place 15 traps, evenly spaced apart, along this first line. Place an additional 15 traps along a second 100 m line 10 m in from the stream bank side of the plot and parallel to the first line of traps.

CONDUCTING THE SMALL MAMMAL TRAPPING

Trapping will be conducted for three consecutive nights at each plot All traps will be set within 2 hours of sunset and checked within 3 hours after sunrise the following morning. Each trap will be baited with peanut butter and rolled oats, and a wad of cotton was placed at the back of each trap for bedding.

Each animal captured will be identified to species, and its age, sex, reproductive condition, and general health will be evaluated and noted. The time, location of capture, and general weather and habitat conditions also will be recorded. Photographs will be taken of each study plot and each new species captured. All data will be recorded on standardized Jones & Stokes field forms

(Attached). Each captured animal will be marked with a permanent nontoxic felt pen so it could be identified as a recapture if trapped on subsequent trap-nights. All animals will be released at the site of capture.

All Jones & Stokes biologists conducting the small mammal surveys will wear appropriate protective clothing and respirators during the handling of the animals to avoid potential exposure to Hantivirus. Standard precautionary measures identified in Mills et al. (1995) *Guidelines for Working with Rodents Potentially Infected with Hantivirus* will be observed during this work.

Once tapping has been completed all traps and flagging will be removed from the site.

POST-FIELD CHECKLIST

- Check over the field data forms and make sure everything is completed and clear.
- Surveyors should review each other's completed forms for completeness and accuracy in the field.
- Photocopy all your field forms. File the copes in the file cabinet in Ted's office and the originals in the Placer Legacy office.
- Cross off, date, and initial your completed site on the master list to ensure that field work is not repeated.
- Report progress to the project manager and obtain additional survey packages.

Draft 19 May, 2003

A KEY TO THE WOODY PLANTS OF RIPARIAN ZONES IN CALIFORNIA"S CENTRAL VALLEY

By John C. Hunter, Jones & Stokes, 2600 V Street, Sacramento CA 95818 jhunter@jsanet.com

1. Plant a large (up to several m high), densely clumped grass, with thick (> 2 cm) woody stems … *Arundo donax* (Giant reed)
1. Plant not a grass … 2
    2. Leaves compound (the thin flat portion of the leaf discontinuous) … 3
        3. Leaves opposite (> 1 leaf attached to stem in same plane) … 4
            4. Leaflets palmately arranged (radiating from a central point), flowers > 1 cm long, fruit with a husk that separates from the large (> 3 cm in diameter) round seed … *Aesculus californica* (California buckeye)
            4. Leaflets pinnately arranged (feather-like, arranged like ribs off a backbone), flowers < 1 cm long and fruits either flat and winged or small (<5 mm across) round and fleshy … 5
                5. Fruits dry and winged (with a thin flat extension), flowers inconspicuous, pith (in center of stem) not particularly large … 6
                    6. Fruit two-parted, each part with a wing; Leaves with 3-7 leaflets; Leaflet margins coarsely toothed … *Acer negundo* (box elder)
                    6. Fruit one-parted with one wing; Leaves with 5-7 leaflets; Leaflet margins smooth or with fine (small) teeth … *Fraxinus latifolia* (Oregon ash)
                5. Fruits fleshy without a wing, pith conspicuously large and spongy, flowers small and white (or cream) but showy in a dense inflorescence (cluster) … 7
                    7. Flowers in a broad flat clusters, Fruits black (sometimes white) with a white waxy coating that causes them to appear blue … *Sambucus mexicana* (Blue elderberry)
                    7. Flowers in rounded to cylindrical clusters, Fruits red, or black, without a waxy covering … *Sambucus racemosa* (Red elderberry)
        3. Leaves alternate (just 1 leaf attached to stem at any perpendicular plane) … 8
            8. Plant a legume (Our woody species in the Central Valley have pea-like flowers in drooping clusters, fruit a dry pod with multiple seeds) … 9
                9. A tree with white flowers, spines at the base of leaves, and a flat pod … *Robinia pseudoacacia* (black locust)
                9. A shrub or small tree with red flowers, no spines, and a pod with four "wings" … *Sesbania punecia*
            8. Plant not a legume … 10
                10. Plant w/ prickles … 11
                    11. Fruits dry, enclosed in a fruit-like fleshy to leathery sac (a rose hip); Leaflets pinnately arranged (feather-like, arranged like ribs off a backbone) … *Rosa californica* (California rose)
                    11. Fruits fleshy, blackberry-like; Leaflets palmately arranged (radiating from a central point) … 12
                        12. Leaves white on underside; Prickles broad-based; Stems often stout and ribbed (ridged); Leaflets 3-5; Flowers/fruits > 10 in each inflorescence (cluster) … *Rubus procerus* (Himilayan blackberry)
                        12. Leaves light green on underside; Prickles slender; Stems round; Leaflets 3; Flowers/fruits 2-15 in an inflorescence … *Rubus ursinus* (California blackberry)
                10. Plant w/o prickles … 13
                    13. Leaflets with a round gland (a thickened dot) near the base, fruit flat, dry with a wing … Ailanthus (Tree-of-Heaven)
                    13. Leaflets without a basal gland, fruit round, fleshy or leathery and without a wing … 14
                        14. Plant a vine or shrub; Leaflets 3-5; Leaflet margins lobed, coarsely toothed or smooth; Fruits small (< 1 cm) … *Toxicodendron diversilobum* (Poison oak)

                        14. Plant a tree, Leaflets 11-19; Leaflet margins sharply toothed but not lobed; Fruits large (> 2.5 cm across) … *Juglans californica* var. *hindsii* (Northern California black walnut)

Draft 19 May, 2003

2. Leaves simple (the thin flat portion of the leaf continuous)
    15. Plant a willow: Fruit a capsule with seeds embedded in cottony fluff; Leaves alternate, deciduous and narrow (ranging from linear (almost not taper) to lance-shaped); Buds covered by a single scale; Bark bitter tasting and astringent with an aspirin-like flavor … 16
        16. Scale covering bud in axil of leaf (where leaf meets stem) has free and overlapping margins (you can see this by pressing down on the tip of the bud and rocking it from side to side); Axillary bud small (< 3 mm), conical and pointed … 17
            17. Leaf dull green on both sides; stipules (a pair of small leafy or dry and papery bracts where the leaf joins the stem) absent; Twigs of the current year tend to be yellow to olive, Plant a tree to 30 m high … *Salix gooddingii* (Gooding's black willow)
            17. Leaf glossy green above and glaucous (waxy white) below; stipules generally present; Current year twigs typically red to yellowish brown; Plant a tree to 14 m … *Salix laevigata* (Red willow)
        16. Scale covering bud in axil has margins fused together so that the scale forms a cap; Axillary bud small to large, with a rounded tip and shape elliptic to conical … 18
            18. Leaves narrow (linear and generally < 1 cm wide) with upper and lower surfaces similar, both covered (thickly or thinly) in silky hairs; Plant a clonal, multi-stemmed shrub to 6 m … *Salix exigua* (Sandbar or Narrow leaf willow)
            18. Leaves broader (elliptic to lance-shaped and generally > 1 cm wide) with upper surfaces shiny green and lower surfaces pale green or glaucous (waxy white), hairs generally restricted to young leaves; Plant a shrub or small tree to 18 m … 19
                19. Petiole (stalk of leaf) with glands at base of blade (these glands appear as small warty, irregular protrusions); Leaves 5-17 cm long, lance-shaped and gradually tapering towards the tip with concave sides (long acuminate)… *Salix lucida* var. *lasiandra*, (Shining willow)
                19. Petiole without glands; Leaves 3-12 cm long, narrowly lance-shaped to elliptic, tapers to tip with convex sides … *Salix lasiolepis*, (Arroyo willow)
    15. Plant not a willow and the complete set of attributes not as above; Fremont's cottonwood is in the willow family and shares some of the traits described above except that its leaves are broad and triangular to heart-shaped and its buds have > 1 scale; For other species: Fruit not a capsule and seeds not embedded in cottony fluff; Leaves alternate or opposite, deciduous or evergreen and narrow or broad; Buds covered by more than one scale; Bark taste varied but without an aspirin-like flavor;
        20. Plant an oak: Fruit an acorn; Buds clustered near the branch tips; Plant a tree … 21
            21. Leaves with bristles *Quercus wislizenii* (Interior live oak) – However, at higher elevations, if underside of leaf has a pale bluish cast and it covered in powdery dust, the plant could be could be *Quercus chrysolepis* (Canyon live oak)
            21. Leaves w/o bristles … 22
                22. Leaves deeply lobed (often > ½ distance to midrib); Acorn 3-5 cm long; Leaves upper surface with a greenish cast … *Quercus lobata* (Valley oak)
                22. Leaves shallowly lobed (< ½ distance to midrib) or wavy margined; Acorn 2-3.5 cm long; Leaves upper surface often with a bluish cast … *Quercus douglasii* (Blue oak)
        20. Plant not an oak: Fruit not an acorn; Buds generally not clustered near branch tips; Plant a tree, shrub or vine … 23
            23. Plant a woody vine … 24
                24. Plant evergreen, lacking tendrils … *Hedera helix* (Ivy)
                24. Plant deciduous and with tendrils opposite leaves … *Vitis californica* (California wild grape)
            23. Plant a shrub or tree … 25
                25. Plant evergreen … 26
                    26. Plant a shrub, often sticky; Flowers in dense clusters (surrounded by bracts so that they almost appear to be a single flower) developing into dry fruits with a tuft of bristles (pappus) at the top … 27
                        27. Leaves up to 15 cm long, narrow with a gradual taper, widest near middle; Leaf stalks (petioles) winged (i.e., having a thin, flat extension running along them) … *Baccharis salicifolia* (mule fat)

27. Leaves up to 5 cm long, broad and strongly tapering to base, often widest above middle; Leaf stalks very short … *Baccharis pilularis* (coyote brush)

26. Plant a shrub or tree, not sticky; Flowers not as above, clearly on separate stalks (pedicels), and fruits fleshy … 28

28. Leaf margin entire (smooth); Fruits 1-3 cm long, green or black when mature … 29

29. Leaves alternate, green on both sides, aromatic … *Umbellularia californica* (California bay laurel)

29. Leaves opposite, green above, silvery below, not particularly aromatic … *Olea europea* (olive)

28. Leaf margin toothed; Fruits about 0.6 cm long, red when mature … *Heteromeles arbutifolia* (toyon)

25. Plant deciduous … 30

30. Leaves opposite or whorled … 31

31. Leaf margins jagged (toothed); Fruit 2-parted, each part with a wing (a thin flat extension), and not splitting open, seeds not hairy … *Acer saccharinum* (Silver maple)

31. Leaf margins smooth; Fruit lacking a wing, seeds with or without a fringe of hairs …

32. Fruits arranged in a dense ball at or near tips of branches, and each fruit composed of two hard, dry pieces; Seeds without a fringe of hairs; Plant a shrub or small tree; Leaves with a dry scale (interpetiolar stipule) between adjacent leaf bases … *Cephalanthus occidentalis* (Button-willow)

32. Fruit a long woody pod; Seeds with fringes of hairs at their ends; Plant a tree; Leaves without scales (stipules) at the base of their stalks … *Catalpa* species (common name also Catalpa)

30. Leaves alternate … 33

33. Leaves small (< 3mm), triangular and close against the stem; Petioles (leaf stalks) absent … *Tamarix parviflora* (Smallflower tamarisk)

33. Leaves larger (> 1 cm), shapes various but not triangular, and spreading away from stem; Petioles present … 34

34. Leaves lobed … 35

35. Leaves 2-5 cm wide and hairless, base of leaf stalk does not completely enclose bud; Plant a shrub … *Ribes aureum* (Golden currant)

35. Leaves 10-20 cm wide and pubescent, base of leaf stalk either encircles stem or completely encloses bud; Plant a large shrub to large tree … 36

36. Leaves and stems exude milky sap when broken; Fruit fleshy; Bark relatively smooth and not flaking … *Ficus carica* (Fig)

36. Leaves and stem do not exude milky sap when broken; Fruit hard and dry with a tuft of hairs, arranged in dense round heads; Bark flakes in thin sheets to reveal smooth pale surface … *Platanus racemosa* (Western sycamore)

34. Leaves toothed but not lobed; Bark varied but not as above; Fruits various but not as above ... 37

37. Leaves triangular to heart-shaped; Petiole (leaf stalk) flattened near leaf blade; Fruit a capsule opening to release small seeds in cottony fluff; Plant a large tree to 30 m … *Populus fremontii* (Fremont's cottonwood)

37. Leaves elliptic to lance-shaped; petiole more or less round, not conspicuously flattened; Fruit not a capsule and seeds not embedded in cottony fluff; Plant a small to large tree … 38

38. Plant with two types of shoots – long and short shoots, the short shoots with closely spaced leaves and also bearing the flowers and fruits; Leaves with lateral veins that fork and bend before reaching the leaf margin (the edge of the leaf) … *Prunus* species (the stone fruits including cherries and almond)

38. Plant with one type of shoot, though these may vary in orientation and spacing of leaves; Leaves with straight lateral veins only some of which fork before reaching the leaf margin … 39

    39. Fruits produced on woody scales arranged in a cone-like structure; Buds on a small stalk, not offset from leaf stalk … *Alnus rhombifolia* (White alder)

    39. Fruits not produced in a cone-like structure; Buds not stalked, offset from leaf stalk … *Ulmus* species (Elm species)

Appendix B
Summary of Species Observations

Table B-1. Frequency of Observed Odonate Species

Common Name	Scientific Name	Total (%) *N = 43*	Placer County Plots (%) *N = 20*	Other Plots (%) *N = 23*
Damselflies	**Zygoptera**			
American Rubyspot	*Hetaerina americana*	47	50	43
Spotted Spreadwing	*Lestes congener*	2	0	4
California Spreadwing	*Archilestes californica*	7	0	13
California Dancer	*Argia agrioides*	19	20	17
Emma's Dancer	*Argia emma*	28	25	30
Sooty Dancer	*Argia lugens*	14	5	22
Aztec Dancer	*Argia nahuana*	2	0	4
Vivid Dancer	*Argia vivida*	40	45	35
Unknown sp. teneral dancer	*Argia* sp.	5	10	0
Boreal Bluet	*Enallagma boreale*	5	5	4
Familiar Bluet	*Enallagma civile*	44	40	48
Unknown sp. female bluet	*Enallagma* sp.	5	5	4
Pacific Forktail	*Ischnura cervula*	42	35	48
Western Forktail	*Ischnura perparva*	5	10	0
Desert Firetail	*Telebasis salva*	2	5	0
Dragonflies	**Anisoptera**			
Blue-eyed Darner	*Aeshna multicolor*	65	75	57
Common Green Darner	*Anax junius*	93	90	96
Pale-faced Clubskimmer	*Brechmorhoga mendax*	42	50	35
Western Pondhawk	*Erythemis collocata*	26	20	30
Eight-spotted Skimmer	*Libellula forensis*	0	0	0
Widow Skimmer	*Libellula luctuosa*	9	10	9
Common Whitetail	*Plathemis lydia*	7	10	4
Twelve-spotted Skimmer	*Libellula pulchella*	9	5	13
Flame Skimmer	*Libellula saturata*	21	0	39
Blue Dasher	*Pachydiplax longipennis*	30	35	26
Red Rock Skimmer	*Paltothemis lineatipes*	5	0	9
Wandering Glider	*Pantala flavescens*	44	40	48
Spot-winged Glider	*Pantala hymenaea*	26	25	26
Variegated Meadowhawk	*Sympetrum corruptum*	51	40	61
Striped Meadowhawk	*Sympetrum pallipes*	5	0	9
Black Saddlebags	*Tramea lacerata*	84	85	83

Table B-2. Observed Butterfly Species

Common Name	Scientific Name	Total (%) *N = 43*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
California Sister	*Adelpha bredowii*	11	13	8
Sara Orange-tip	*Anthocharis sara*	6	9	4
Field Skipper	*Atlopedes campestris*	23	35	13
Pipevine Swallowtail	*Battus philenor*	72	70	75
Persius Duskywing	*Erynnis persius*	2	0	4
Northern Checkerspot	*Charidryas palla*	4	4	4
California Ringlet	*Coenonympha tullia*	45	70	21
Orange Sulphur	*Colias eurytheme*	77	74	79
Monarch	*Danaus plexipus*	0	0	0
Propertius Duskywing	*Erynnis propertius*	6	4	8
Mournful Duskywing	*Erynnis tristis*	2	4	0
Common Checkerspot	*Euphydryas chalcedona*	4	0	8
Eastern Tailed Blue	*Everes comyntas*	51	57	46
Gorgon Copper	*Gaeides gorgon*	2	0	4
Fiery Skipper	*Hylephila phyleus*	6	13	0
Buckeye	*Junonia coenia*	96	96	96
Lorquin's Admiral	*Limentis lorquini*	15	30	0
Purplish Copper	*Lycaena helloides*	4	9	0
Mourning Cloak	*Nymphalis antiopa*	11	17	4
The Farmer	*Ochlodes agricola*	4	9	0
Pale Swallowtail	*Papilio eurymedon*	2	4	0
Western Tiger	*Papilio rutulus*	70	78	63
Anise Swallowtail	*Paplio zelicaon*	13	17	8
Umber Skipper	*Paratrytone melane*	13	22	4
Common sSoty-wing	*Pholisora catullus*	2	0	4
Mylitta Crescent	*Phyciodes mylitta*	34	52	17
Cabbage Butterfly	*Pieris rapae*	89	91	88
Acmon Blue	*Plebejus acmon*	30	17	42
Sandhill Skipper	*Polites sabuleti*	2	4	0
Satyr Comma	*Polygonia satyrus*	4	0	8
Checkered White	*Pontia protodice*	2	4	0
Common Checkered	*Pyrgus communis*	4	0	8
California Hairstreak	*Satyrium californicum*	17	17	17
Hedge-row Hairstreak	*Satyrium saepium*	0	0	0
Sylvan Hairstreak	*Satyrium sylvinus*	11	9	13
Common Hairstreak	*Strymon melinus*	28	48	8
West Coast Lady	*Vanessa annabella*	4	0	8
Red Admiral	*Vanessa atalanta*	34	43	25
Painted Lady	*Vanessa cardui*	55	61	50
American Lady	*Vanessa virginiensis*	6	13	0

Table B-3. Amphibian and Reptile Species Observed During One Survey of Plots

Common Name	Scientific Name	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
Pacific Treefrog	*Pseudacris regilla*	2	4	0
Foothill Yellow-legged Frog	*Rana boylii*	0	0	0
Bullfrog	*Rana catesbeiana*	32	26	38
Western Pond Turtle	*Emys marmorata*	0	0	0
Western Fence Lizard	*Sceloporus occidentalis*	28	26	29
Western Skink	*Eumeces skiltonianus*	0	0	0
Aligator Lizard	*Elgaria* sp.	13	4	21
Gopher Snake	*Pituophis catenifer*	2	0	4
Garter Snake	*Thamnophis* sp.	2	0	4
Western Rattlesnake	*Crotalis viridis*	6	4	8

Table B-4. Amphibian and Reptile Species Observed During Four Surveys of Plots

Common Name	Scientific Name	Total (%) *N = 12*	Placer County Plots (%) *N = 8*	Other Plots (%) *N = 4*
Pacific Treefrog	*Pseudacris regilla*	8	0	25
Foothill Yellow-legged Frog	*Rana boylii*	8	13	0
Bullfrog	*Rana catesbeiana*	42	38	50
Western Pond Turtle	*Emys marmorata*	8	0	25
Western Fence Lizard	*Sceloporus occidentalis*	83	88	75
Western Skink	*Eumeces skiltonianus*	0	0	0
Aligator Lizard	*Elgaria* sp.	33	50	0
Gopher Snake	*Pituophis catenifer*	8	13	0
Garter Snake	*Thamnophis* sp.	0	0	0
Western Rattlesnake	*Crotalis viridis*	8	0	25

Table B-5. Mammal Species Observed During One Survey of Plots

Common Name	Scientific Name	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
Virginian Opossum	*Didelphis virginiana*	2	0	4
Desert Cottontail	*Sylivlagus audubonii*	4	4	4
Black-tailed Jackrabbit	*Lepus californicus*	11	13	8
Western Gray Squirrel	*Sciurus griseus*	19	22	17
Botta's Pocket Gopher	*Thomomys bottae*	9	4	13
American Beaver	*Castor canadensis*	6	0	12.5
Coyote	*Canis latrans*	6	9	4
Racoon	*Procyon lotor*	40	35	46
Northern River Otter	*Lontra canadensis*	2	0	4
Bobcat	*Lynx rufus*	9	9	8
Mule Deer	*Odocoileus hemionus*	34	26	42

Table B-6. Mammal Species Observed During Four Surveys of Plots

Common Name	Scientific Name	Total (%) *N = 12*	Placer County Plots (%) *N = 8*	Other Plots (%) *N = 4*
Virginian Opossum	*Didelphis virginiana*	8	13	0
Desert Cottontail	*Sylivlagus audubonii*	8	0	25
Black-tailed Jackrabbit	*Lepus californicus*	17	13	25
Western Gray Squirrel	*Sciurus griseus*	33	38	25
Botta's Pocket Gopher	*Thomomys bottae*	8	0	25
Deer Mouse	*Peromyscus maniculatus*	8	0	25
California Meadow Mouse	*Microtus californicus*	17	13	25
Feral Dog	*Canis familiaris*	8	0	25
Coyote	*Canis latrans*	17	25	0
Gray Fox	*Urocyon cinereoargenteus*	8	0	25
Raccoon	*Procyon lotor*	75	75	75
Feral Cat	*Felis catus*	17	25	0
Bobcat	*Lynx rufus*	17	13	25
Mule Deer	*Odocoileus hemionus*	67	63	75
Muskrat	*Ondatra zibethicus*	8	0	25

Table B-7. Mean Abundance of Small Mammals Trapped at Plots[1]

Common Name	Scientific Name	Total *N = 10*	Placer County Plots *N = 6*	Other Plots *N = 4*
Opossum	*Didelphis virginiana*	0.1 ± 0.1	0.2 ± 0.2	–
Brush Mouse	*Peromyscus boylii*	3.5 ± 2.3	–	8.8 ± 5.1
Deer Mouse	*Peromyscus maniculatus*	5.1 ± 1.8	2.0 ± 1.6	9.8 ± 2.5
California Meadow Mouse	*Microtus californicus*	3.2 ± 2.5	1.2 ± 0.7	6.3 ± 6.3
House Mouse	*Mus musculus*	1.3 ± 0.9	0.8 ± 0.8	2.0 ± 2.0
Black Rat	*Rattus rattus*	0.6 ± 0.2	0.7 ± 0.3	0.5 ± 0.3

[1] Values are means ± 1 standard error.

Table B-8. Bird Species Observed During One Survey of Plots

Common Name	Scientific Name	Summer Resident	Migrant	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
Pied-billed Grebe	*Podilymbus podiceps*	X		2	4	0
Great Blue Heron	*Ardea herodias*	X		2	4	0
Green Heron	*Butorides virescens*	X		2	0	4
Wood Duck	*Aix sponsa*	X		2	4	0
Mallard	*Anas platyrhynchos*	X		11	17	4
Cinnamon Teal	*Anas cyanoptera*	X		2	4	0
Common Merganser	*Mergus merganser*	X		0	0	0
Turkey Vulture	*Cathartes aura*	X		4	4	4
White-tailed Kite	*Elanus leucurus*	X		2	0	4
Cooper's Hawk	*Accipiter cooperii*	X		2	4	0
Red-shouldered Hawk	*Buteo lineatus*	X		11	13	8
Swainson's Hawk	*Buteo swainsoni*	X		2	4	0
Red-tailed Hawk	*Buteo jamaicensis*	X		6	0	13
American Kestrel	*Falco sparverius*	X		0	0	0
Ring-necked Pheasant	*Phasianus colchicus*	X		2	4	0
Wild Turkey	*Meleagris gallopavo*	X		4	9	0
California Quail	*Callipepla californica*	X		17	13	21
Common Moorhen	*Gallinula chloropus*	X		2	4	0
American Coot	*Fulica americana*	X		2	4	0
Killdeer	*Charadrius vociferus*	X		9	4	13
Spotted Sandpiper	*Tringa macularia*	X		0	0	0
Mourning Dove	*Zenaida macroura*	X		28	26	29
Barn Owl	*Tyto alba*	X		0	0	0

Table B-8. Continued

Common Name	Scientific Name	Summer Resident	Migrant	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
Great Horned Owl	*Bubo virginianus*	X		0	0	0
Black-chinned Hummingbird	*Archilochus alexandri*	X		17	17	17
Anna's Hummingbird	*Calypte anna*	X		32	30	33
Belted Kingfisher	*Megaceryle alcyon*	X		11	9	13
Acorn Woodpecker	*Melanerpes formicivorus*	X		30	48	13
Nuttall's Woodpecker	*Picoides nuttallii*	X		60	52	67
Downy Woodpecker	*Picoides pubescens*	X		40	39	42
Hairy Woodpecker	*Picoides villosus*	X		2	0	4
Northern Flicker	*Colaptes auratus*	X		11	4	17
Western Wood-Pewee	*Contopus sordidulus*	X		32	26	38
Willow Flycatcher	*Empidonax traillii*		X	13	22	4
Dusky Flycatcher	*Empidonax oberholseri*		X	2	4	0
Pacific-slope Flycatcher	*Empidonax difficilis*	X		19	22	17
Black Phoebe	*Sayornis nigricans*	X		51	61	42
Ash-throated Flycatcher	*Myiarchus cinerascens*	X		68	70	67
Western Kingbird	*Tyrannus verticalis*	X		30	26	33
Hutton's Vireo	*Vireo huttoni*	X		9	13	4
Warbling Vireo	*Vireo gilvus*	?		28	30	25
Western Scrub-Jay	*Aphelocoma californica*	X		57	65	50
Yellow-billed Magpie	*Pica nuttalli*	X		19	26	13
American Crow	*Corvus brachyrhynchos*	X		2	4	0
Common Raven	*Corvus corax*	X		0	0	0
Tree Swallow	*Tachycineta bicolor*	X		38	26	50
Northern Rough-winged Swallow	*Stelgidopteryx serripennis*	X		15	4	25
Cliff Swallow	*Hirundo pyrrhonota*	X		4	0	8

Table B-8. Continued

Common Name	Scientific Name	Summer Resident	Migrant	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
Barn Swallow	*Hirundo rustica*	X		2	4	0
Oak Titmouse	*Parus inornatus*	X		53	61	46
Bushtit	*Psaltriparus minimus*	X		57	61	54
White-breasted Nuthatch	*Sitta carolinensis*	X		51	65	38
Bewick's Wren	*Thryomanes bewickii*	X		40	26	54
House Wren	*Troglodytes aedon*	X		55	74	38
Western Bluebird	*Sialia mexicana*	X		9	4	13
Swainson's Thrush	*Catharus ustulatus*		X	9	0	17
American Robin	*Turdus migratorius*	X		30	30	29
Wrentit	*Chamaea fasciata*	X		15	26	4
Northern Mockingbird	*Mimus polyglottos*	X		13	17	8
European Starling	*Sturnus vulgaris*	X		40	48	33
Cedar Waxwing	*Bombycilla cedrorum*		X	2	0	4
Phainopepla	*Phainopepla nitens*	X		0	0	0
Orange-crowned Warbler	*Vermivora celata*	X		19	22	17
Nashville Warbler	*Vermivora ruficapilla*		X	2	0	4
Yellow Warbler	*Dendroica petechia*		X	21	13	29
Common Yellowthroat	*Geothlypis trichas*	X		11	9	13
Wilson's Warbler	*Wilsonia pusilla*	?		30	17	42
Yellow-breasted Chat	*Icteria virens*	X		30	22	38
Western Tanager	*Piranga ludoviciana*		X	26	22	29
Black-headed Grosbeak	*Pheucticus melanocephalus*	X		45	35	54
Blue Grosbeak	*Guiraca caerulea*	X		4	0	8
Lazuli Bunting	*Passerina amoena*	X		19	22	17
Spotted Towhee	*Pipilo maculatus*	X		28	30	25

Table B-8. Continued

Common Name	Scientific Name	Summer Resident	Migrant	Total (%) *N = 47*	Placer County Plots (%) *N = 23*	Other Plots (%) *N = 24*
California Towhee	*Pipilo crissalis*	X		19	9	29
Lark Sparrow	*Chondestes grammacus*	X		2	0	4
Savannah Sparrow	*Passerculus sandwichensis*	X		2	0	4
Song Sparrow	*Melospiza melodia*	X		26	26	25
Red-winged Blackbird	*Agelaius phoeniceus*	X		13	17	8
Western Meadowlark	*Sturnella neglecta*	X		13	13	13
Brewer's Blackbird	*Euphagus cyanocephalus*	X		11	0	21
Brown-headed Cowbird	*Molothrus ater*	X		51	30	71
Bullock's Oriole	*Icterus bullockii*	X		32	13	50
House Finch	*Carpodacus mexicanus*	X		49	43	54
Lesser Goldfinch	*Carduelis psaltria*	X		45	57	33
American Goldfinch	*Carduelis tristis*	X		45	48	42
House Sparrow	*Passer domesticus*	X		9	9	8

Table B-9. Bird Species Observed During Four Site Visits

Common Name	Scientific Name	Summer Resident	Migrant	Total (%) *N = 12*	Placer County Plots (%) *N = 8*	Other Plots (%) *N = 4*

Appendix B

Central Valley Songbird Responses to Riparian Width and Other Site- and Landscape-Scale Habitat Characteristics

Appendix B
Central Valley Songbird Responses to Riparian Width and Other Site- and Landscape-Scale Habitat Characteristics

Introduction

To address Placer County's interest in developing riparian setback guidelines for conservation purposes, we analyzed six years of riparian bird count data with respect to width of the riparian zone. Using a subset of PRBO bird survey sites, supplemented by new sites in Placer County, Jones & Stokes (2004) detected a positive relationship between riparian bird species richness and riparian zone width. Thus we wanted to investigate whether additional relationships could be detected using our comprehensive Central Valley riparian point count dataset. In our analysis, we also examined local vegetation and GIS-generated habitat types and surrounding landscape characteristics. Our primary goal was to characterize songbird relationships with riparian zone width, and to identify appropriate widths for riparian buffer zones (development setbacks), given a range of habitat and landscape characteristics.

Methods

Data used for analysis were obtained from bird point count surveys (Ralph et al. 1993) conducted between 1998 and 2003. Sites included long-term monitoring sites along the Sacramento, Cosumnes and San Joaquin Rivers, as well as sites that were surveyed for shorter periods of time, primarily for inventory purposes (Figure B-1). We used a total of 596 riparian point count stations along 117 streamside transects (Table B-1). Within each transect, points were spaced at least 200 meters apart, and the first point count survey station was selected using a random starting point. Point counts were conducted for five minutes, with 1-3 visits per season. (See http://www.prbo.org/tools/pc/pcprot.doc for detailed methods.)

For each of the 596 survey points, we calculated riparian species richness (as defined in Jones & Stokes 2004) as a cumulative value across all surveys. We also obtained a mean abundance across all surveys for each of these riparian-associated species, as well as presence/absence. A variable representing the number of surveys upon which the species richness and presence/absence values were based was retained in all models, to account for the fact that species richness increases with the number of surveys.

Using standard GIS data layers, point count stations were classified into two general categories, tributary or mainstem, as well as identified by drainage basin (DWR CalWater 2.2), elevation, and dominant vegetation cover type (WHR category based on best available GIS data layer) (Tables B-2 to B-5).

For each point we also calculated surrounding landscape characteristics within a 1-km radius, as well as the dominant surrounding land use—urban, agricultural, or "natural" (everything else). Land use and vegetation types were aggregated into more meaningful categories for analysis (Table B-5). We used three different GIS layers for these calculations:

1. Land use (DWR multi-year composite) (Figure B-2)
2. Vegetation (CDFG/DU 1993 wetlands where available; USFS existing vegetation multi-year composite elsewhere) (Figure B-3)
3. Riparian vegetation (union of available datasets: Chico State Sacramento River, San Joaquin River, CDFG/DU wetlands, DWR land use, Placer County vegetation)

Vegetation data were collected for each point count location using a modified relevé protocol (Ralph et al. 1993, Ralph et al. 1995) within a 50-m radius (see http://www.prbo.org/tools/pc/relevepr.html for detailed methods). A subset of variables representing major structural characteristics was used for this analysis (Table B-5). To reduce the number of variables considered, and because riparian zone width was of primary interest in our analysis, floristic composition variables were not analyzed.

Regression models were developed for riparian-associated bird species richness (as defined by Jones & Stokes 2004), as well as presence/absence of each of these species. We used multiple linear regression for species richness, and logistic regression (Hosmer and Lemeshow 1989) for each individual species' occurrence. Three classes of regression models were developed and compared with respect to the relative importance of riparian width as a predictor of bird species richness / occurrence. The dependent variables for each of these model classes were:

- Riparian width category only
- Riparian width category + potentially significant vegetation and landscape variables (from Pearson correlation analysis, $\alpha = 0.10$)
- Riparian width category + basin, vegetation type (WHR) and stream type

Models were first constructed using a numerical riparian width value (1 = 0-50 m, 2 = 50-100 m, 3 = >100 m), treated as a continuous variable, to test for linear relationships between riparian width and bird species richness and individual species' probability of occurrence. To evaluate differences between each of our three width categories (<50 m, 50-100 m, >100 m), we reran the models treating

Table B-5. Definition of Independent Variables Used in Regression Analysis

Variable name	Definition
Riparian width (field-collected)	
width2	riparian width category: 1 is 0-50 m, 2 is 50-100 m, 3 is >100 m)
Geography / habitat variables	
elevation	elevation (m)
huname / huname2	basin name (see Tables 2-4)
whr_new	WHR habitat type (see Table 4)
strm_type	stream type (mainstem or tributary)
Landscape-level vegetation variables	
rip_cov	proportion of riparian cover within a 1 km radius
agric_veg	proportion of agricultural vegetation within a 1 km radius
herb_veg	proportion of grassland vegetation within a 1 km radius
shrub_veg	proportion of shrub vegetation within a 1 km radius
wtlnd_veg	proportion of wetland vegetation within a 1 km radius
forest_veg	proportion of forest vegetation within a 1 km radius
Lanscape-level landuse variables	
agric_use	proportion of agricultural landuse within a 1 km radius
natur_use	proportion of natural landuse within a 1 km radius
urban_use	proportion of urban landuse within a 1 km radius
Site-level (field-collected) vegetation variables	
canopycov	canopy cover
treecov_new	absolute percent cover of the tree layer (>5 m in height); may contain vegetation that is not strictly a tree, such as vines hanging from trees, so long as its within the height range
shrubcov_new	absolute percent cover of the shrub layer (0.5-5 m in height); may contain non-woody plants within the height range
herbcov_new	absolute percent cover of the hebraceous layer (<0.5 m in height); may contain small shrubs and other woody plants less than .5 meters high
hitreeht	*average* height of the upper bounds of the tree layer
hishrubht	*average* height of the upper bounds of the shrub layer
maxtrdbh	maximum diameter at breast height to the nearest 0.1 centimeters, for the tree layer

width as a categorical variable and tested for equality of means within each width category.

This process was repeated for just the subset of point counts representing tributary streams, as well as for the subsets of data representing each dominant land use type within 1 km (agriculture, natural or urban).

Because we were interested in the effect of riparian width, with and without controlling for environmental conditions, we compared the model coefficient for riparian width across the three model classes. We recognized that riparian width could be affected by surrounding landscape characteristics, which may in turn affect local vegetation characteristics. Thus the apparent effect of riparian width could increase or decrease when controlling for other variables that are more strongly associated with a given bird metric. Our approach was intended to identify additional environmental variables associated with the bird metrics in question, and perhaps help explain the importance of riparian width. But we also wished to detect the responses to riparian width that may be obscured by other variables in a more complex model.

Results

Without controlling for any other environmental variables, riparian width was a significant positive predictor of riparian-associated bird species richness, as well as the presence of Black-headed Grosbeak (BHGR) and Common Yellowthroat (COYE) (Table B-6). Blue Grosbeak (BLGR) presence was negatively associated with riparian width. Controlling for the effect of geography (basin, elevation) and habitat type (WHR type and stream type), all of these species except COYE had a reduced, but still significant response to riparian width category, as did species richness. Only BHGR was positively associated with riparian width, and BLGR was negatively associated with riparian width, after also controlling for vegetation and surrounding land use characteristics (Table B-6).

Species richness and BHGR presence were positively associated with riparian width at mainstem, but not tributary sites, while the reverse was true for Yellow Warbler (YWAR) and COYE (Table B-7). For the Song Sparrow (SOSP), there was a significant positive relationship with riparian width at tributary sites, but a negative relationship at mainstem sites (Table B-7). BLGR presence was negatively associated with riparian width only at mainstem sites (Table B-7).

Comparing dominant surrounding land use categories (agricultural or natural), the relative importance of riparian width varied across species. For species richness, the effect was greater in natural than agricultural landscapes (Table B-8). For BHGR and BLGR probability of occurrence, the positive/negative effect of riparian width was greatest in natural landscapes. Warbling Vireo (WAVI) displayed a negative association with riparian width only in natural landscapes, while COYE and SOSP showed significant associations with riparian width only within agricultural landscapes (Table B-8).

Controlling for riparian width and site vegetation, we found a positive association between species richness and the proportion of riparian and wetland vegetation within a 1 km radius (Table B-10). With respect to individual species, we found that (Table B-10):

- YWAR was negatively associated with surrounding agricultural proportion within 1 km;
- BHGR and YWAR were negatively associated with surrounding grassland proportion;
- BLGR was positively associated with surrounding grassland proportion;
- SOSP and YBCH were positively associated with the proportion of surrounding natural land uses;
- YBCH was negatively associated with surrounding wetland proportion; and
- WIFL was positively associated with the proportion of surrounding forest.

Although we found a positive, linear effect of riparian width on species richness, tests for equality of means revealed a significant difference between widths greater than 100 m and those less than 100 m, but could not discriminate between widths less than 100 m (i.e., <50 m vs. 50-100 m) (Table B-6, Figure B-4). The same was true for YWAR and COYE probability of occurrence (Table B-7). However, for BHGR probability of occurrence, there was a threshold at 50 m, with a significant difference between width categories 1 (<50 m) and 2 (50-100 m), as well as between category 3 (>100 m) and category 1 (<50 m).

Summary and Recommendations

Our results indicated that, in California's Central Valley, the number of riparian songbird species was significantly lower where the riparian woodland zone was less than 100 m in width, at least along mainstem river corridors. Four species were also less likely to occur in riparian areas less than 100 m wide: the Black-headed Grosbeak, Common Yellowthroat, Yellow Warbler (a California Bird Species of Special Concern), and Song Sparrow. For the latter three species, this positive response to riparian width was only detected along tributary creeks, while for the Black-headed Grosbeak, it was only along mainstem rivers.

In addition, we found a strong influence of surrounding land use (within a 1-km radius) on which and how many riparian songbird species occurred at a site. The number of species increased with the amount of riparian and wetland habitat found within a 1-km radius. With respect to species composition, we found that the Yellow Warbler was negatively associated with the amount of agricultural land use within 1 km, and that the Song Sparrow and Yellow-breasted Chat were positively associated with the amount of “natural” (i.e., non-agricultural and non-urban) land use. Because few of our study sites were in urban areas, we were not able to evaluate the effect of urban development directly.

(2) See Table 5 for definitions of vegetation and landscape variables.

These findings suggest that, in order to maintain current populations of riparian-associated bird species, riparian woodlands and other natural vegetation should be maintained within at least 100 m on either side of all streams. To restore populations of species that are in decline (e.g., Yellow Warbler) or locally extirpated (e.g., Song Sparrow), the condition of riparian woodlands should be actively enhanced and restored within this zone. The Riparian Bird Conservation Plan (RHJV 2004) lists several recommendations for enhancing riparian habitat for birds and wildlife, which include managing for a diverse understory, increasing the diversity of woody plants, control of invasive plant and animals, and timing of management activities, such as mowing and grazing, to avoid the breeding season. To conserve greater riparian bird diversity, riparian setbacks and activity restrictions should be implemented not only in rural residential and urban areas, but also in agricultural zones.

It is also important to recognize the importance of landscape context in determining habitat suitability for riparian songbirds. The preservation, restoration and linkage of large parcels of undeveloped and uncultivated lands will provide significant benefits to riparian songbird species. Conservation priorities should be large contiguous areas of riparian vegetation surrounded by "natural" uplands to the greatest extent possible. Restoration priorities should be stream segments with large areas of nearby existing riparian habitat.
